# Preface

INSTRUCTION in the technic of survival under difficult conditions is and always will be a vital part of the Naval Aviation Physical Training Program. Naval aviators and other flight personnel are flying and fighting throughout the entire world and it is unwise to assume that all of them will return, to land safely on their carrier or home base. Many will be forced down in strange waters and on strange lands and it is desired by the Chief of Naval Operations that these officers and men be armed with absolutely all the information and technics available, to enable them to return safely to live and fight again.

This manual on survival has been prepared for the specific purpose of teaching trainees sound and tried methods of surviving on both land and sea. Aviation personnel consists of officers and men from all walks of life, and thus many of them have not had sufficient background to prepare them for the difficult combat life ahead. It is therefore both desirable and essential that all aviation personnel become familiar with the material in this manual and practice the methods and technics outlined herein, in order that if the occasion arises, they may put this material to practical use in overcoming the forces of nature that often combine to prevent their safe return.

This manual has been prepared by the officers in charge of the instruction of the Survival Program in the Naval Aviation Physical Training Program.

F. T. WARD

Captain, U.S.N.

Director of Aviation Training

Office of the Chief of Naval Operations

Navy Department

# Introduction

THIS MANUAL has been prepared to meet the need for essential yet comprehensive information on the technic of survival under unusual conditions. It is designed for use both by instructors and trainees in Naval Aviation. It treats survival on a global basis, emphasizing principles that can be grasped quickly and easily and practiced to the benefit of any person subjected to the hazards of warfare. These general principles are supplemented where necessary with specific information.

This manual has been made as complete as is practical in the realization that a thorough knowledge of this subject gives confidence, aids in conquering fears of the unknown, and will serve as the foundation for making sound decisions. General and universally applicable principles formulated out of man's contact with nature throughout the ages have been set down and organized so as to enable the individual to make maximum use of this knowledge at a time when survival may depend on the ability to apply it. Knowledge acquired from this manual supplemented by field exercises offers the most practical method of giving sound individual instruction in a given period of time. Our fighting men must be prepared to enter battle zones with a maximum chance of survival. No matter where stranded they must have every aid to assist them to both live and fight again.

In preparing such a manual, it would be impossible to rely upon information from any one source and a general acknowledgment is made to those individuals and institutions who throughout the years have recorded even the remotest of facts in order that such information might be available for the benefit of mankind. Various governmental agencies have furnished illustrations and their scientists have constructively reviewed this manual. Among these are the Smithsonian Institution, the Bureau of Entomology and Plant Quarantine, the Bureau of Plant Industry, the Fish and Wildlife Service, the Special Forces Section O.Q.M.G. and the Emergency Rescue Equipment Section. The Library of Congress and the Department of Agriculture Library have also been most helpful.

HOW TO SURVIVE  
ON  
LAND AND SEA

*Air warfare has made the world so small that mountains, deserts, jungles, and oceans may all pass below you in a single flight. Anywhere in the world may be an emergency landing spot. Be prepared to survive and return to fly and fight again.*

## CHAPTER I

# Survival Hints

In a world-wide war of movement, you may suddenly find yourself stranded in unfamiliar conditions and surroundings in the Arctic, on the ocean, on a coral island, or in the jungle, or desert. You may tend to magnify the hazards of these strange places because of this unfamiliarity. Fear of the unknown weakens you by reducing your ability to think and plan. If you are armed with knowledge acquired beforehand, no part of the world will be completely strange or frightening to you. You will be capable of coping with the new surroundings and returning to your base in good physical and mental trim.

Survival in the jungle, desert, and arctic country depends largely on resourcefulness. Your chances of success will be greatly increased *if you are physically fit, if you are dressed and equipped for an emergency, if you know fundamental woodcraft principles and can to some extent apply them, and if you have at least a limited skill in a number of outdoor technics.* To feel at home in the wilderness you must learn to know it just as you have learned to know your home or city. You must learn what can be used for food, where to look for it, and how to prepare it. You must know how to care for your body, how to conserve energy, where to sleep, how to take shelter, and how to tell where you are at all times. Likewise, you must familiarize yourself with those things in the environment that will harm you. It is not an easy task, but you can do it.

Many forces will be operating against you to reduce the length of time you can survive. Food and water are always critical, but other factors such as warmth, shelter, and disease may also be hazardous, depending upon the conditions.

So many different emergency situations may confront you in a global war that it is impossible to lay out any definite survival formulae. The best assurance, therefore, that you can overcome all such adverse factors when on your own is to possess basic information on survival.

With even an elementary knowledge of fundamental woodcraft principles, you would not worry, for example, about a tiger being the cause of an unfamiliar night noise in our North American woods because you would know that tigers "can't happen here." Likewise, you would not waste valuable time and effort attempting to catch fish with a hook if you know that it is almost impossible to hook that particular species of fish because of its feeding habits.

FIG. 1. Individual Survival Equipment. A. Sheath Knife; B. Pocket Fishing Kit; C. Wrist Compass; D. Waterproof Matches and Case; E. Pencil Flashlight; F. Mosquito Head Net.

You may remember that a net or spear will do the trick, and know the method of making one from materials at hand. You may be covered with mosquito bites, but you are not concerned about contracting malaria in the North when you know that malaria is a disease of warm climates. Such elementary knowledge will enable you to eliminate many needless fears and absurd possibilities. Your survival time will be in direct proportion to the knowledge and skill you have at your immediate command, your ability to improvise successfully, and intelligently to apply specific information in supplying your immediate needs.

### ***Be Prepared with Emergency Equipment***

Well-considered preparation, made while you have time to prepare, will help you when an emergency comes. Every airman should take care to be dressed to cope with the physical conditions of the area over which he must fly and fight. He should have proper gear aboard his plane or on his person before he starts on a flight. The best kit is useless to a pilot who has crash-landed if the kit is on his bunk on the carrier or at the base 400 miles away. Planes *must* be checked before takeoff to see that necessary items are aboard.

The following items in your pockets or attached to your belt at all times will be excellent insurance, regardless of whether or not you also are carrying emergency and first-aid kits:

1. A strong pocket *knife* or sheath *knife*, preferably the latter.
2. *Waterproof matches* or matches in a waterproof container.
3. A small *waterproof compass*.
4. A *pencil flashlight* in a waterproof container.
5. A *shirt-pocket fishing kit*. This should consist of a dark lightweight fishing line, cadmium plated hooks (especially small sizes as most of the easily available food fish are small) and a small gold spinner with red and white streamer fly.
6. A *mosquito head net* is of great importance in jungle or arctic country, or wherever insect pests are numerous. Such a net will fold up no larger than a handkerchief.

This list is by no means exhaustive. The emergency kit should be carefully examined and additions made depending upon the type of country over which you must operate. Keep in mind, then, that a magnifying glass, a light harpoon-type spearhead, a side arm with shot shells (or shot shells that will fit your regular side arm) a light jungle hammock, a pocket size, one-burner gasoline stove, a first aid kit, rations, canteen, a small signalling mirror, a light down sleeping bag, a machete, and so on, are all of value.

### **Think Before Acting**

When you are forced down on land in strange country, stick by your plane if there is a chance of rescue. It is easy to see, and may furnish a good shelter and base of operations. If you are in enemy territory, abandon the plane, first salvaging anything that can be of value to you in your trek to your own territory. Then sabotage the plane. Make a pack out of your parachute harness, cut a section of silk for a tent and hammock, save the shroud lines for a rope, and, if necessary, the rest of the silk for a blanket.

Over any considerable period you must have food, but remember that if water is available, if the body is not overexerted, and if the climate is warm, you can live off your muscle and fat for weeks. Don't eat if you lack water as eating uses up the body's water reserves. Determine a course to follow, and travel slowly. Don't exhaust yourself by pushing blindly and hurriedly on with a single objective in mind—to get out. Rather, your first consideration must be to keep physically and mentally fit. Start looking for food and water before you become too tired or exhausted to do so effectively. Prepare a bed and sleep when you become tired. Conserve your strength, and remember to observe and think so that when you act, you act intelligently.

### **Seeking Food**

All food is either plant or animal, and is interrelated and distributed according to definite laws. There is order underlying the diversity in nature and this order will help you in searching for food. Since animals depend on plants for food, animal life is usually scarce where plant life is scarce.

Remember that climate is the greatest single factor affecting the abundance and distribution of plant and animal life. *Certain vegetative regions may be found throughout the world in more than one zone (Arctic, Temperate or Tropic) but wherever these regions occur they will have essentially the same appearance and will contain similar types of plants and animals.* Map I shows the distribution of these world vegetative regions where the problems of surviving and living off the land will be basically similar.

Within these regions are still smaller areas such as streams, lakes, marshes, swamps and various types of forests and grasslands, in which live specific characteristic forms of life. These areas are still further subdivided, and each subdivision has animals and plants peculiar to itself and all interrelated. Such areas are known as habitats.

This distribution greatly simplifies the search for food. If you know the edible animals and plants of North America and their habitat you can safely find and eat similar animals and plants in other parts of the world. Likewise your knowledge of one jungle or desert region may help you out of a similar spot on the other side of the earth.

Every climate and area will have some forms of life which are familiar to you, and some which are new but usable. Look for edible plants and animals in distant countries in the same type of places that you found them at home. If you hunted squirrels at home, you will know where to look for squirrel-like animals in other parts of the world. If you know where and how to look for crayfish, clams, rabbits or various birds at home, remember that similar regions abroad will have similar forms of life which you can seek in the same way.

More than half the task of obtaining food lies in knowing what to expect in a given area and where and how to look for it. You would not, for example, expect to find the coconut palm at high altitudes or in a dense forest, but in low, sandy, sea shore areas or on river flood plains. In an emergency, you might not start out to look for a particular type of food, but you will have a general idea of what to look for as you travel through different types of country, and can plan your course so as to enter areas where you can expect to find certain plants or animals.

Every animal is closely associated with a number of other animals living near it. A bird or animal beyond reach may still be a means of getting food if you make use of its presence intelligently. The fact that the bird or animal is there, indicates that its food source probably also is nearby, and it may be a source of food for you, too. If, for example, you see several hawks flying up at your approach, a careful search of the ground may disclose traces of mice, rabbits, or lizards, all sources of emergency food. On the arctic tundra a great snowy owl flitting ahead of you tells more plainly than words that you can expect to find mice or lemming beneath the snow or vegetation. A snake dropping into a jungle stream may startle you, but it should also let you know that a careful search may reveal an available source of food. Snakes are themselves edible, and they live exclusively on animal food. Water snakes live largely on fish, frogs, tadpoles and crayfish. These are all good eating for you, too, and are usually abundant where water snakes are found. Swarming bees may lead you to honey or to the bee grubs which natives consider a delicacy. Squirrels and related animals may be far out of reach, but their food supply of nuts, fruits, buds, seeds or leaves should be where you can get it. Diving terns, boobies, kingfishers or pelicans often indicate a good fishing spot. These are only a few examples of how plants or animals may point the way to food sources because all are intricately related by food chains. There are many more which you can use.

### ***Testing Food***

Never eat large quantities of a strange food without first testing it. If other foods are not available, eat a little of the strange one, and then wait a

while. A small quantity of even a poisonous food is not likely to prove fatal or even dangerous, whereas a large quantity may be. In general it is safe to try foods that you observe being eaten by birds and mammals, but there are some exceptions. Food eaten by rodents (mice, rats, rabbits, beavers, squirrels, muskrats) or by monkeys, baboons, bears, racoons and various other omnivorous animals usually will be safe for you to try. Unknown plant foods with milky juices should be avoided. Any plant parts with an unusually bitter or otherwise disagreeable taste are not only unpleasant to eat but may be definitely harmful.

Throughout the world there are almost endless sources of food.

Plants, whether water or land, furnish edible:

Fruits	Buds	Nuts
Seeds	Leaves	Stems
Bark	Flowers	Roots
Tubers	Sap	Shoots
	Pods	

Edible animals vary infinitely:

1. Land mammals are easily recognized by their covering of hair. All are edible.
2. All birds and birds' eggs can be eaten.
3. Amphibians and reptiles (frogs, salamanders, toads, snakes, lizards and turtles) are good sources of edible meat.
4. Various other smaller forms of animal life may be the most available foods at a specific time and place. They include:

Shellfish—clams, mussels, snails.

Crustaceans—crayfish, crabs, shrimps, pawns.

Insects—ants, termites, grasshoppers, locusts are numerous and are worldwide in distribution.

5. Animal byproducts include:

Eggs—of birds, turtles.

Honey—It can be found during most of the year, and is made by various types of bees.

Caches—Fruits, nuts, seeds and roots are stored by mice, lemmings, squirrels, chipmunks.

## CHAPTER II

# Orientation and Traveling

One of your first problems when isolated in strange country is to determine approximately where you are and what direction you must travel in order to reach a base. The best insurance against getting lost in the event of a forced landing is to know the country over which you are going to fly. You can learn a great deal by studying maps, charts and photographs at every opportunity. Notice the general direction of flow of the larger rivers, the direction in which mountains or prominent ridges run, features of the shore line, the location of outstanding landmarks, *and their relationship to your base.*

If you're abandoning ship or plane at sea and have time, a notation of course and direction to the nearest land and of the latitude and longitude, will be most useful. If your watch is running and protected against crash or water damage it will help. Previously note the direction of prevailing winds and the flow of ocean currents, as these will determine the movement of your raft to a large extent. One may be favorable, the other unfavorable. With a favorable current and unfavorable wind, you can get farther by keeping the raft and yourself as low in the water as possible. Use of a sea anchor or drogue will increase the effect of the current. In a favorable wind, ride high by lightening the raft as much as is practical and hoist a makeshift sail.

*If you find yourself lost on land, sit down, think the situation through, and don't be in a hurry to do anything.* Try to avoid panic by divorcing from your mind any worry of the future. When you are calm and thinking clearly, see if you can recall to mind landmarks you saw from the air. Climb a high tree or hill and attempt to get your bearings.

If this does not give you a clue, you may experience a sense of utter isolation. Don't despair; restrain your impulse to push on, force yourself to observe, and remember that the worst fears are those of the imagination, and your greatest enemy is not the wilderness, but yourself.

Before you go anywhere, determine the cardinal directions from sun or stars and lay a course of travel. If you have a map or chart, it will be less difficult for you to establish where you are and where you wish to go.

The first step is to orient the map—with a compass if you have one, or if not, by the sun or the stars. Orienting a map consists simply of making north on the map coincide with true north. To orient with a compass, lay the map out flat, place the compass on it, and turn the map until the north-south grid lines are parallel to the compass needle, with map north coinciding with the

FIG. 2. Get a Clear View, Determine Your Course and Follow Your Compass

FIG. 3. Orient Map, Then Lay a Course of Travel

compass north. Then rotate the map and the compass together until the needle indicates the amount of magnetic declination (variation) for that area. The map is then oriented, and all directions on the map coincide with those on the ground. To determine the bearing you must follow to reach your destination, place the center of the compass over your own position on the oriented map. This is determined by an approximation or through the recognition of landmarks. A line from the center of the compass to your proposed destination will give you the bearing to follow. Remember that "compass north" is *magnetic* north, and that in most areas it is not the same as *geographic* north. The North Star gives you *geographic* north. Take heed of metal objects near your compass that may affect the reading.

If you are lost to such an extent that you do not know in which direction to travel in order to reach familiar territory, then a compass will only enable you to continue in a straight line along any course you choose.

### CELESTIAL GUIDES

On land or sea, the sun and stars will guide you.

#### *Sun*

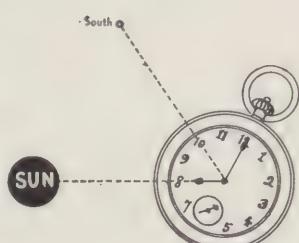

You can determine direction from the sun's position at any time of day, as well as in early morning and late evening.

The zenith is the point in the sky directly overhead. In the northern hemisphere, the path of the sun is distinctly south of the zenith in winter, and almost overhead during summer. At noon in winter the sun will be due south of you. In the southern hemisphere the situation is reversed.

In the tropics, the noon sun will be roughly either east or west of you, or directly overhead.

Notice where the sun strikes you when facing in the direction you want to travel. Relate its position to your direction frequently, and use it to help average your detours if you must follow a winding course.

In the northern hemisphere, a watch set by local sun time can be used to determine direction. Point the hour hand toward the sun. South will be half way between the hour hand and 12:00. On cloudy days, if the watch is held so that the shadow of a stick held upright at the center falls along the hour hand, North will be one half the distance between the shadow and 12:00 on the watch. These will give you only a rough approximation, and are not useful near the poles.

### Stars

In the northern hemisphere, the two end stars on the bowl of the Big Dipper point to the North Star (Polaris) which is the last star in the handle of the Little Dipper. You can make a rough determination of your latitude by use of the fact that it is approximately the same number of degrees as the height of the North Star above the horizon.

In the southern hemisphere, a line through the long axis of the Southern

FIG. 5. Big Dipper

FIG. 6. Orion

Cross points to the south pole. There is no guiding star above it—only a blank space in the sky so dark by comparison that it is known as the "Coal Sack."

East of the True Cross are two very bright stars. By using these and the True Cross as guides, you can locate a spot within the Coal Sack which is approximately above the south pole. (See Figure 7.)

Extend a line along the long axis of the Southern Cross, to the south. Join the two bright stars east of the Cross by a line. Bisect this line with one at right angles. The point at which this line intersects the line through the Cross is approximately above the south pole.

Orion, an old friend of starry nights at home, is visible in most latitudes and will help you locate other familiar stars.

Near the equator, a star rising directly east of you will pass directly overhead and set directly west. In the northern hemisphere, that part of the horizon where the low stars move horizontally across the sky is the southern horizon. In the southern hemisphere, it is the northern horizon.

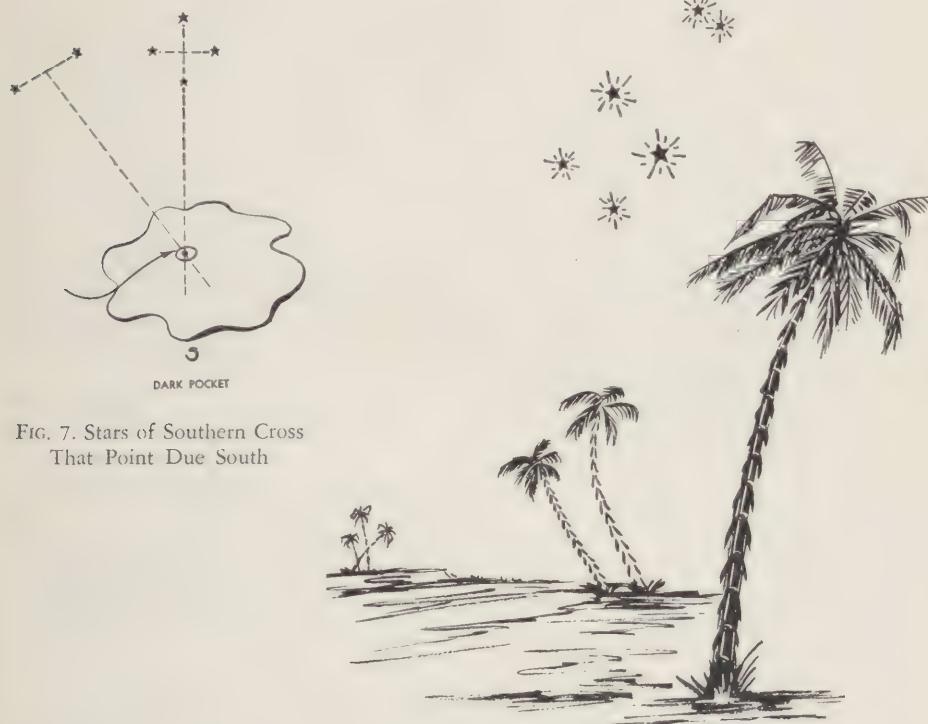

FIG. 7. Stars of Southern Cross  
That Point Due South

FIG. 8. Southern Cross

### KEEPING A COURSE

The sun by day and the stars by night are valuable guides for maintaining a course, but they are not always visible, and you may in any case need to use additional methods. In strange country, observe outstanding features of the landscape and concentrate on keeping your course.

Observation from a high point, whether tree or ridge, will permit you to note the drainage patterns, the trend of ridges or mountains, and the character of the vegetation in an area.

If possible, choose a prominent landmark in the desired direction of travel that can be seen en route. Relate the position of the sun to yourself and the

distant landmark. As you approach this landmark, line up another farther away. In dense forests where distant landmarks can't be seen, you can hold a course by lining up three trees. As soon as you pass one of these, line up another beyond the next two. Look back occasionally to note the relative positions of landmarks, slope and contour of the ground; for country looks entirely different when viewed from different observation points.

Streams, ridges, trees and bluffs will generally guide you in open country and enable you to retrace your route if it should be necessary. On cloudy days, in dense vegetation, or wherever the country presents a sameness of appearance, mark your trail with blazes, bent bushes, overturned logs, or rocks. Bushmarks are easily made, and should be cut or bent in such a manner that the under and lighter side of the leaves are uppermost. Such a sign is conspicuous in dense country.

Utilize trails when they are going in your general direction. You must look carefully for them as they may be well hidden, particularly in tropical rain forests and dense jungle country. At a fork, take the most traveled path and keep a lookout for traps and pitfalls on game trails.

If you lose your course or trail, stop and try to remember how long it has been since you were sure of your position. Mark the spot where you are with a pile of rocks, a bent bush, or blazes on four sides of a tree—marks you can see from some distance and any direction. Then you can start hunting or "back tracking" for your trail with the assurance that you can at least recognize the spot from which you started should you circle or choose the wrong direction. Don't travel by night in strange wooded country except in an emergency. In open or desert country, with the aid of the moon or stars, it is fairly simple and convenient. It may be the *only time* to travel in desert areas.

A light should be used at night only to read a map or compass, or in particularly rough or dangerous spots. Your eyes will adjust to darkness in a short time, while with a light you are blinded to everything outside the small area of illumination.

In open country you can hold a reasonably accurate course at night by selecting a fairly bright star near the horizon in your direct line of travel, and continuously lining it up with trees and other skyline landmarks ahead. Since stars appear to move from east to west due to the earth's rotation, you should check your direction frequently by the North Star or Southern Cross, and choose a new guide star when the old one moves out of position.

If you have a compass, check the magnetic bearing of your guide star every 15 minutes if the star is in the general direction of north or south, or every 30 minutes if it is east or west.

### Detours

In rough country frequent detours must be made, and you should know how to compensate for them to get back on your course. Methods of doing this include:

1. In short detours, estimate the distance and average the angle of departure. On your return, gauge the angle and distance so as to strike your line again. For greater accuracy count paces and use a compass.
2. Select a prominent landmark ahead of you and one behind you on your line of travel. On returning from your detour, walk until you are again "lined up" on the two landmarks, then follow your original course.

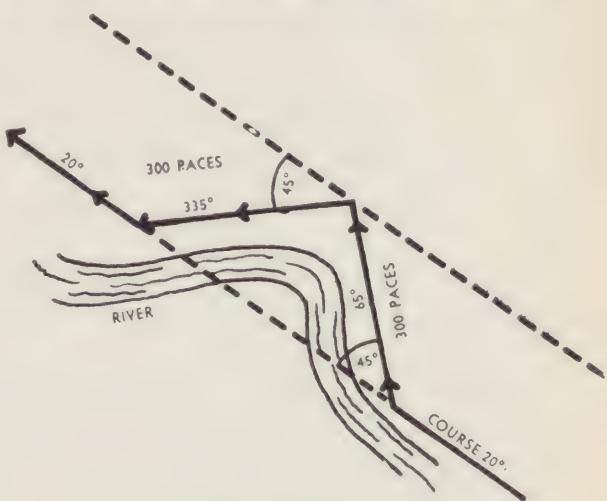

FIG. 9. Averaging Angle of Departure and Angle of Return

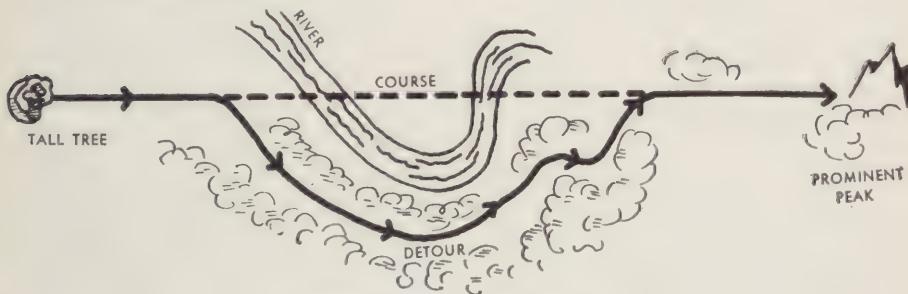

FIG. 10. Use of Landmarks

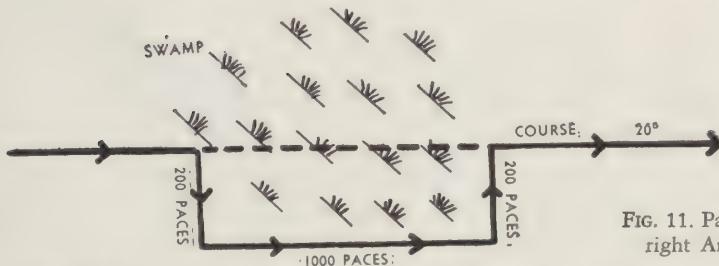

FIG. 11. Paces and right Angles

3. An easy way to compensate is by paces and right angles, although it requires more walking. (See Figure 11.)

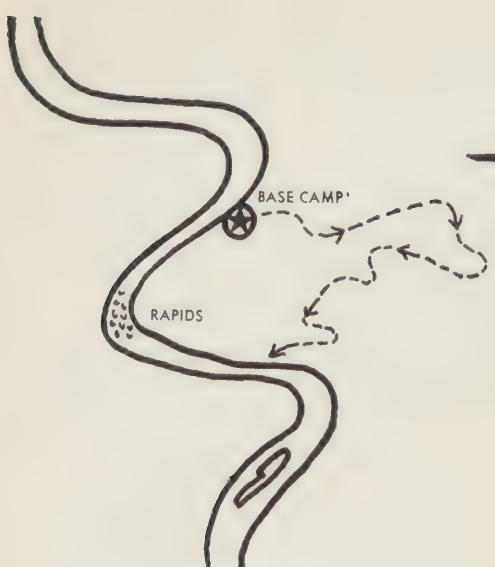

FIG. 12. Stream Base Line

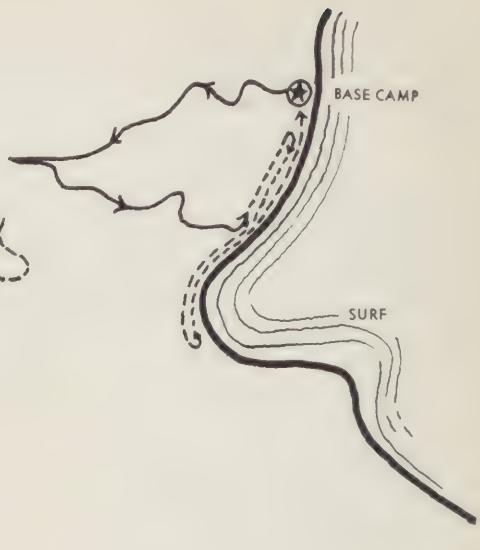

FIG. 13. Shore Base Line

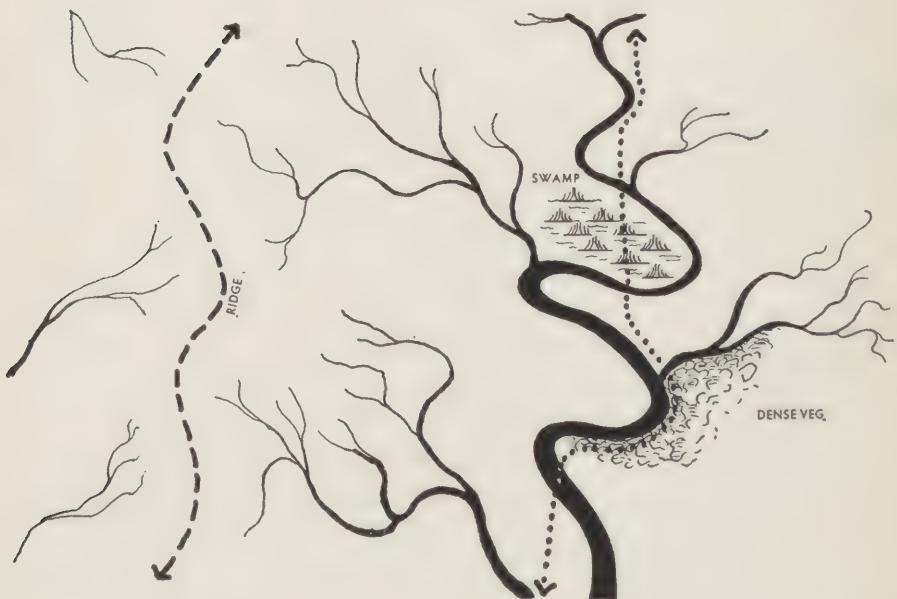

FIG. 14. Divide

### ***Base Lines***

If you have a more or less permanent camp site and want to explore unknown country, establish a base line at right angles to your intended reconnaissance direction. Any continuous line such as ridge, escarpment, range of hills, streams, seashore, or line of blazed trees or bushmarks will serve.

Explore the base line for several miles in each direction, noting characteristics you can remember so that you will know your approximate location on it when you strike it again. With a base line established, you can leave camp in search of food or water with reasonable assurance that you can return. As an example, let's assume that you are camped on a seashore. You leave camp, headed west in search of food or water. You know you have to go east to get back, but on your return you may veer from your course and strike the beach well above or below your camp.

If you have explored the beach for several miles each way from camp, you'll *know* whether you're above or below camp, and can travel back in the right direction. If you haven't established a base line, you may go several miles in the wrong direction, hunting camp, and then have to retrace your steps. You may cover 10 or 15 miles in getting to a camp only three miles away. (See Figures 12 and 13.)

### **TRAVEL HINTS**

Whether you'll choose to travel on ridges and divides or follow valleys or streams; whether you'll follow trails or cut across country—these and many other questions will be determined by the situation in which you find yourself and the vegetation and topography of the area.

### ***Ridges and Divides***

Traveling on a ridge or divide is often easier than hiking in a valley or along a stream. Vegetation is usually less dense, the ridge itself serves as a guide, outlooks are frequent, and there will be few tributary streams or swamps to cross. On divides, be careful not to stray off on an intersecting ridge going the wrong direction.

### ***Streams and Valleys***

Following a stream generally requires much fording, detouring and penetration of thick vegetation. In mountain country there will be falls, cliffs, and side canyons. In flat country, the stream will meander, the vegetation will be dense, outlooks will be rare, and swamps common. Even so, it presents many advantages in strange country. It gives you a definite course which may lead to inhabited areas, and will also be a source of food, water, and a means of travel by boat or raft.

### ***Shore Lines***

A shore area may be easy or difficult to travel, but is almost always long and circuitous. Nevertheless, it is an excellent base line and food area, and a good place to "stick to" until you can orient yourself and lay a course for a known objective.

### ***Jungle Brush or Dense Woods***

Move through dense vegetation in one direction, but not in a straight line. Turn your shoulders, shift your hips, bend your body and shorten or lengthen, slow or speed your pace, as the situation requires. Avoid obstructions instead of fighting them. Keep alert, watching your surroundings generally and the ground in front of you closely. Stop and remain motionless now and then. You can thus hear or see an enemy, check your bearings, and locate animals. Rest frequently. A slow, steady rate of travel with rest as needed will get you much farther in the long run than a rate which will exhaust you in a short time.

### ***Care of the Feet***

Be sure your shoes fit well and that your feet are always in shape for a long walk. Heavy wool socks are best for hiking even in a warm climate, since they prevent chafing and absorb perspiration. Spare socks are a help, but if you can't change, you can at least wash those you have on, since dirty ones chafe and increase the danger of infection.

*Attend to blisters or sprains at once.*—Remove pressure on blisters by cutting your shoes or improvising footgear from canvas, plant fibers, or parachute silk. Don't break a blister. Prick the edge of it with a knife blade or thorn made sterile by flame or boiling. Then press out the fluid and keep the blister clean and dry, using a disinfectant if you have one. If infection develops, a day's rest may be well worth while. If you have salt, soaking an infected foot in hot salt water will help.

Wet shoes make the feet tender. Stop and dry them out if practicable.

A sprained ankle doesn't always swell or hurt immediately. If you give an ankle a bad wrench, bandage at once. Cold applications and rest will reduce the swelling and pain.

### ***Concealment***

In enemy territory, make use of natural cover and be sure that you have nothing on you that will reflect light or otherwise attract attention. Stop often to look and listen. Move quickly if crossing an exposed spot, and avoid silhouetting yourself against a contrasting background or the skyline. Conceal your trail by traveling on hard ground or in water. Avoid disturbing animal

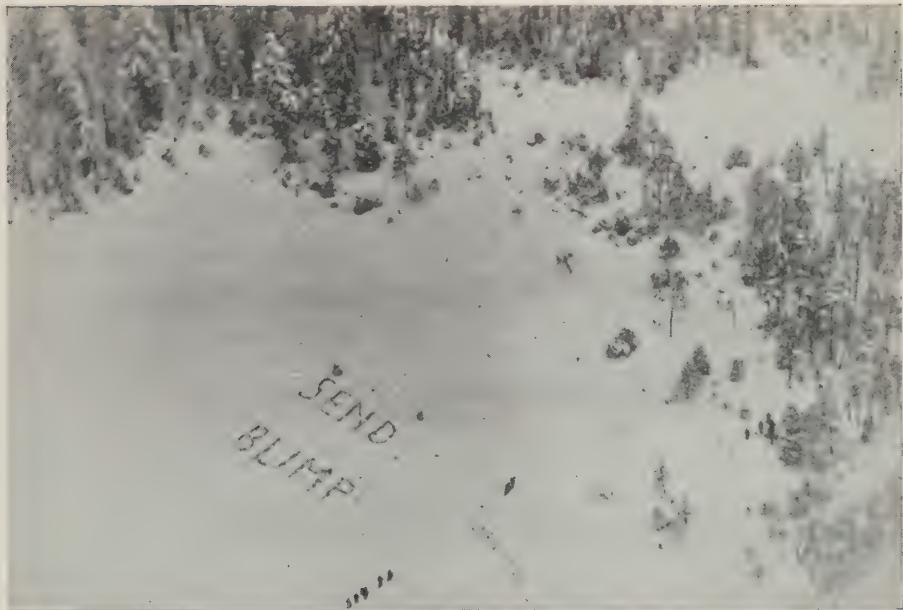

FIG. 15. Signalling in the Snow with Evergreen Branches (Coast Guard)

life. Always look from the *dark* into the *light*. When danger threatens, never peer into the dark from a camp fire. By putting your head close to the ground and looking up you can see silhouettes against the night sky and remain unseen.

### Signalling

Methods of making your whereabouts and needs known to rescuers include:

**Signs**—In snow you can tramp out letters or make them with evergreen branches. Against sand you can use shells, stones, or vegetation.

**Smoke and Fire**—You can produce heavy smoke by making a large fire and smothering it with damp vegetation, or by throwing engine oil on a fire.

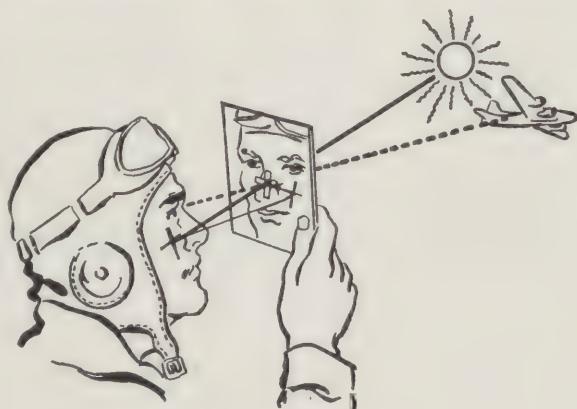

FIG. 16. Signalling with Mirror

*Flags*—Parachutes spread against a dark background, or white clothing waving in the wind, will attract attention over moderate distances.

*Mirrors*—An aimed beam of light from a mirror made of any shiny material may be effective up to 10 miles on clear days. (See Figure 16)

Make a mirror from a food tin, or something else that is shiny on both sides. Punch a cross-hole in the center of the mirror and sight through the cross at the ship or plane with the mirror held about three inches in front of the face. The spot of light coming through the hole onto your face can be seen in the back mirror. Move the mirror so the cross of light on your face *disappears in the hole in the mirror, at the same time keeping a sight on the plane or ship*. The beam from the front of the mirror will then be aimed properly. You cannot signal when directly in line with the sun and the ship you want to attract. Some emergency kits now have special signalling mirrors.

### WATER TRAVEL

Streams, small and large, may present special hazards to you when trying to get back to your base.

FIG. 17. Use a Pole to Cross Swift Shallow Currents—Note Parachute Pack on Back

A stout pole, for use as a brace, will help you cross a shallow, swift stream. If the current is slow and the bottom rocky, keeping your body submerged will take most of the weight off your feet and reduce the danger from bruises. Cross deep, swift currents by swimming diagonally downstream.

In flat country the outsides of river bends generally have steeper banks and

FIG. 18. Swim Down Shallow Rapids Feet First on Your Back

FIG. 19. Inflate Trousers to Keep Your Feet Up

FIG. 20. Go Head First, on Your Belly in Deep Rapids

deeper and swifter water than inner curves. Cross diagonally and strike the inside of a bend where the water is apt to be slack and shallow. Often the current is slow and shallow at the widest part of a stream. Just above a riffle, water is generally shallow. Use a log or small raft if the stream is wide, or you are a poor swimmer.

Rapids or swift water usually are not as dangerous as they look or sound. Never fight the current. Always swim *with* it and try to keep horizontal, to reduce the chance of being pulled under. *Go feet first, on your back, down fast, shallow rapids*, and "fin" your hands alongside your hips for buoyancy and as fenders against submerged rocks. Keep your feet *up* to avoid getting them bruised or caught by rocks. *Go head first, on your belly, down deep rapids* and angle toward shore as opportunity offers. Breathe between wave

FIG. 21. Don't Get Broadside to a Current

troughs. Be careful of backwater eddys and converging currents; they often contain dangerous swirls. Avoid bubbly water under falls as it has little buoyancy.

Don't take a chance in cold water, as your limbs will numb rapidly. Get something to hang onto, even if you are a strong swimmer.

If you must cross thin ice, distribute your weight even to the extent of lying down and pushing yourself along. When pulling yourself out of a hole in ice, place your hands on the ice, kick your feet until your body is level, then swim onto the ice and roll to a safe place. Don't stand up.

#### *Canoes, Dugouts, Rafts*

The easiest way to follow the course of a stream frequently will be to use it as a highway by means of a canoe, dugout, or raft.

If you can find a friendly native with a dugout, your travel troubles will be over. Since you may find the canoe and not the native, a little practice in canoe-handling will be useful. If there are no native craft available, you'll have to make and pole a raft.

Assuming that you're lucky enough to find a canoe or dugout but haven't handled one before, here are a few tips:

1. Keep your weight low, to reduce the chance of turning over.
2. Kneel amidships on one knee and paddle from this position. Paddle from the bow in a strong wind.
3. If you turn over, stay with the canoe. Climb into it over the bow or stern.
4. To paddle a straight course, pull your strokes straight back instead of following the contour of the canoe. Toward the end of each stroke turn the blade so that the inside edge is up. A short pull or shove with the turned paddle at the end of the stroke will turn the bow in the desired direction. The end of the canoe in which you are sitting will always move in the direction opposite to that of your paddle stroke.
5. Put the weight of your body behind each stroke. Don't paddle with your arms alone.

FIG. 22. Pick Your Course Before Starting Through Rapids

FIG. 23. Build a Raft and Follow a Stream to the Sea

Going *downstream* takes caution and quick action if the water is swift, particularly in rapids. Never enter rapids without first looking them over. Choose a course that will avoid rough water as much as possible. Locate submerged rocks. A split current indicates a rock close to the surface, a wave, a deeper rock. Don't get broadside to the current and don't hesitate too long in selecting a channel between rocks.

Going *upstream*, don't fight the current. Use eddies and back currents on the downstream side of rocks and shore projections. Paddle up in the lee of these projections, bucking the current only when necessary to shoot across the channel from one relatively calm spot to another. Hug the inside of bends, and cross fast water at an angle.

Poling a canoe or dugout is more efficient than paddling for going either up or down shallow rapids, or along a shallow protected coastline.

To pole a canoe or dugout, stand amidships, facing to one side. Drop the pole to the bottom so that it strikes directly below you. Slide your hands down and immediately lean forward, applying your weight backward against the pole while your hands alternately change position on the pole, "climbing" toward its upper end hand over hand.

If you can't find a canoe or dugout, two or more logs bound together will

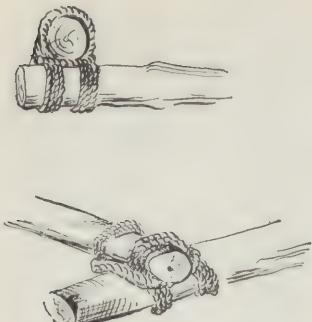

FIG. 24. Raft Lashing

serve as a raft for crossing or navigating a river. Many tropical trees will sink even when the wood is dead, so be sure the wood you choose for a raft will float. Stranded drift logs are the most readily available material. Float several such logs to a convenient spot and lash them together with bark. Dry and soft woods make better rafts than green or hard woods. Bundles of bamboo bound together with vines and lashed to cross pieces make an excellent raft. Palms do not float well.

### *Swimming in Aquatic Vegetation*

While underwater and floating plants make swimming difficult, it is perfectly possible to swim through relatively dense vegetation. Keep calm, don't thrash about, and remove the plants as you would clothing, staying as near to the surface as possible, and swimming the breast stroke, with shallow arm or leg motion. Deep powerful strokes will entangle you. When you get tired, float or swim on your back.

### *Bogs, Quagmires, Muskeg, Quicksand*

Swim, instead of attempting to walk, in any medium that won't support your weight. Muck, mud or sand will support your weight better than water, and you can float in water. The difference is that struggling or lifting your feet *while in a standing position* in muck or sand will only make you sink deeper. *If you feel yourself sinking, fall forward on your face, spread your arms, and start to swim or pull your way along, keeping your body horizontal.* In swampy areas, emergent vegetation usually indicates the ground is firm enough to support your weight. It probably will not be in areas of open mud or water, but if you are even a moderate swimmer you can swim, crawl, or pull your way through miles of bog or swamp.

You can get added buoyancy (as in water) by tying your pants at the ankles and forming air-pockets in the legs. You can also form air pockets over your shoulders by blowing your breath inside the front opening of your collar. Such a sack will keep your head from going under if you get caught in a vertical position, or need a rest.

Quicksand is sand held in suspension by water. It varies in depth and is usually, though not always, localized in area. Quicksands usually resemble ordinary sands and generally occur on flat shores, in silt-choked rivers with shifting water courses, and near the mouths of large rivers. Pebbles on sand are usually an indication the sand is not "quick" and you can test sand

FIG. 25. Flatten Out in Bog or Muck

FIG. 26. Forty Feet of Muck, but You Can Swim Through It

about which you are doubtful by tossing a small stone on it. The stone will sink in quicksand. In quicksand, as in a bog, flatten out, keep your lungs full of air, and move slowly. Quicksand exerts greater pressure than mud or muck.

### ***Mangrove Swamps***

Mangrove swamps occur along coastlines throughout the tropics. Wait for low tide before going through one. If you are on the shoreward side, look for a narrow area of trees and work seaward through these or follow the bed of a waterway or creek. In shallow water there is danger from crocodiles. Leave the water and scramble over the mangrove roots, or follow the soft mud banks. From the seaward side work inland along streams or channels. A raft is the best means of crossing a large swamp area.

### ***Swimming in Surf and Currents***

Knowledge of the action of the tides, currents, and surf will help you should you ever have to swim through them. In unknown waters, use the side or breast stroke to keep a reserve of strength for emergencies.

As waves break, they become higher, shorter, and the shoreward side curves to form a breaker. The water in a breaker, unlike that in an unbroken wave, actually moves forward instead of just seeming to do so. Small waves break in shallow water, large waves farther out.

If the surf is moderate, you can ride a small wave in by swimming forward with it as the crest picks you up, then surface-dive to end your ride just before the wave breaks. *If the surf is high, swim shoreward while in the trough between waves. As the next wave approaches, face the incoming breaker, submerge, and then work shoreward after it passes over.* Waves may break on reefs and bars miles from shore. Look for a channel or opening (indicated by the waves continuing shoreward unbroken). When swimming out through surf, wade as far as possible before swimming, dive under the breakers as they roll toward you and shove forward off the bottom as you come up.

*Wave backwash or undertow* is an outbound current set up by the seaward escape of water piled up on shore by breaking waves, and may be quite dangerous in the case of large waves. If you are caught in the backwash of a large wave, push off the bottom or swim to the surface, and ride shoreward on an incoming wave.

There are several types of dangerous marine currents which should be avoided if possible. *If you do get caught in a current, don't fight it. Swim parallel to the shore or diagonally across it as you would in a river current, heading shoreward only after you are out of the current.*

*Rip currents* are formed by the seaward escape of the water from waves which have broken over offshore bars or barrier reefs; runback occurs at the lowest point of the bar or reef. A similar outward current occurs where the backwash or the outgoing tide is confined to a narrow channel between rocks or shore projections. The water in a current is often murky or sandy in appearance, and usually will be deeper than adjacent waters. At ebb tide the waves in these currents are choppy and appear to be going out to sea instead of shoreward.

*Strong tidal currents* occur along many coasts and may carry you out to sea if you are caught in them. Tides on open, exposed coasts may average six

FIG. 27. Rip Current—Swim Across It to Calm Water and Then Shoreward

to eight feet, but may run to 30 or 40 feet and higher in narrow estuaries. In general, *high powerful tides* can be expected off rocky irregular shorelines, with alternating bays and promontories and *surf and rip currents* can be expected off low coastlines fringed with sandy bars, or coral reefs.

### *Fringing Coral Reefs*

Fringing coral reefs extend out from the shore, forming shallow platforms. Coral is sharp, and severe cuts will result from swimming in a surf breaking over reefs. Go through a break in the reef, or go ashore opposite the mouth of a stream or wherever you see a depression or valley in the shore line, since coral cannot live in fresh water. This however, may involve going against a

current unless the tide is with you. Openings in the reefs may also be discovered by the action of the breakers. Waves that do not break on the reef, but continue their run toward shore, indicate a channel or area clear of coral.

### ***Heavy Seas***

In heavy seas, swim with the wind at your back, keeping as much of your

FIG. 28. In a Rough Sea Swim with Your Back to the Wind

body submerged as possible to avoid wave slap. Plunge through breaking waves; don't attempt to swim over them.

### ***Cramps***

Stomach cramps can be avoided almost entirely by not entering the water too soon after eating and by relaxing while swimming. Muscle cramps generally occur in very cold water or when the muscles are fatigued. At the first indication of muscle cramp, try not to use the muscle involved. Continued pressure and kneading of the knotted muscle will release the cramp.

### ***Running a Boat Shoreward Through Surf***

The greatest danger in running shoreward before a broken sea or in surf

is that the boat may either be caught and thrown end over end or be turned broadside to the waves and capsized. A surf or roller overtaking the boat throws up the stern and depresses the bow. The forward motion of the boat must be sufficiently retarded to allow the surf to pass.

A sea anchor will check the boat's way and keep it end-on to the waves, reducing the danger of capsizing. A make-shift sea anchor can be made from a canvas bucket, a bundle of clothing, driftwood, a life jacket, or any object which can be fastened to a line and made to float, partially submerged, from the stern. Be liberal with the amount of line used.

If the surf is running high, go inshore against a current; the water will be deeper and the waves smaller there.

The surf will be less dangerous on a lee shore than on a windward shore.

#### ***Working a Boat Seaward Through Surf***

Against a strong wind and heavy surf, a boat must have all possible speed as it approaches the crest of a wave, so as to pass through the crest as rapidly as possible and avoid being turned broadside or thrown end-over-end. Avoid meeting a large wave at the moment of breaking. If there is only medium surf, and no wind or an offshore wind, the boat must not be allowed to pass so rapidly through a wave that it falls suddenly after topping the crest.

If a boat turns over in the surf, fall out on the *seaward* side and grab hold of the boat.

#### **TRAVEL IN MOUNTAINOUS OR OTHER ROUGH TERRAIN**

Mountainous or deeply eroded country offers special difficulties. What appears as a single ridge and valley from a distance may prove to be numerous ridges and canyons, all of which must be crossed before reaching the main ridge. Snow fields which drop off in a sheer cliff may blend with those beyond to give the appearance of a continuous line of easy travel.

*Your best bet in the mountains is to follow valleys or ridges; do not try to go at right angles to them.* If you strike a blind canyon with nearly perpendicular walls, start over and try another route. Game trails may show you the best path.

If you must climb or descend a cliff, first attempt to choose a route that appears to offer hand and footholds, cracks, and ledges that offer an unbroken path from top to bottom. Chimneys are vertical cracks or troughs in a wall, and offer a variety of holds.

In climbing cliffs:

1. Test every hold carefully before trusting your weight to it.
2. Distribute your weight on two or more spots, particularly on loose rock.

When standing, keep your feet apart.

3. Be cautious of getting into tight spots where you can't go either direction without danger.
4. Don't climb on loose or rotten rock. Remove loose stones as you descend, so they won't fall on you from above.
5. Keep your balance and keep moving, as a continuous movement from one hold to the other conserves strength. Use your legs as lifting power and your hands mainly for balance.
6. Use a rope, if possible, for descending steep cliffs or slopes. (See rappelling below.)
7. Keep your face, not your back, to the cliff, on a vertical descent.

### *Descending Cliffs*

A rope for use in descending a cliff can be made by twisting four to six parachute shroud lines together.

*Rappelling* is a technic of using the friction of a rope against the body

FIG. 29. Keep Constantly Alert in Mountainous Country

in making a steep or vertical descent. (It is good for abandoning ship, as well as descending a cliff.) It combines a maximum of safety with a minimum of effort. If you're too weak to climb down a rope, you can still rappell down, rest on the way, and save the rope for future use.

To rappell, pass the rope around a tree or rock where it will not bind. Straddle both ropes and wrap them around one thigh, across the chest, over

FIG. 30. Rappelling

the opposite shoulder, and down across the back to be grasped by one hand. Grasp the rope in front of the body with the other hand. The arm that reaches forward is on the opposite side of the body from the encircled thigh. (See Figure 30.) Ease the grip of the hands and drop down in spurts, keeping the body more or less perpendicular to the cliff. The feet should be apart and against the cliff when possible. Slow or stop your drop by tightening your grip. After you get down, retrieve your rope. If there is no necessity

FIG. 31. Rappelling

FIG. 32. Climbing in a Spanish Bowline

for reuse of the rope, it can be tied single instead of double. Rappelling requires a heavy shirt and trousers to avoid rope burns.

When two people are present, one of the safest methods of descent is for one man to lower the other in a seat formed from a Spanish bowline. Use two ropes if possible. Secure one rope firmly to a tree and drop it over the cliff. Give the other rope a turn around the tree, get into the Spanish bowline, and let your comrade pay it out as you descend. The last man will have to rappell down.

#### *Talus Slopes*

A talus is a steep slope composed of loose rock at the base of a cliff. If it is of fine material, turn slightly sideways, keep

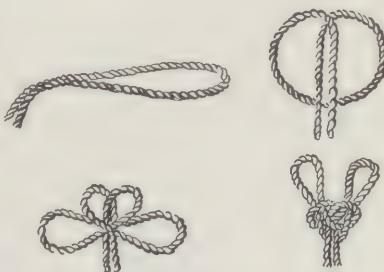

FIG. 33. Spanish Bowline

FIG. 34. Avoid Getting Caught on a High Peak in a Storm

FIG. 35. Glissading Down a Snowfield

your joints loose and go down on a diagonal course, taking long steps or jumps. If the talus is of coarse materials or large rocks, go more carefully, as a loose rock may roll under your weight.

### *Mountain Snowfields and Glaciers*

The easiest and quickest method of getting down a steep snowfield may be to slide or glissade down, standing, using a short, tough stick which can

FIG. 36. Apply Pressure Gradually

FIG. 37. Snow Cornice

be dug into the snow to slow or stop your descent if you should fall. Beware of crevasses which are lightly covered with snow, or invisible from a distance.

Ice crevasses are particularly apt to occur on glaciers at right angles to the glacier flow. They seldom go all the way across the glacier, and thus may be detoured. Test a snow bridge across a glacier with a long pole before attempting to cross.

Kick or cut steps in a steep snow slope if you must cross it. Be on the lookout for avalanches of snow or rock, especially during thaws or in cold weather after a fresh snow. Rock falls are frequent in rugged mountains. Avoid traveling at the base of slopes or cliffs where you may be struck by them.

In topping a snow-covered ridge from the windward side, you may pass

FIG. 38. Climbing Coconut Palm

FIG. 39. Shinnying

FIG. 40. Right Way

FIG. 41. Wrong Way

the sound part of the ridge and walk out on a snow cornice that will break under your weight. From the leeward side, you can see such a cornice. Follow the ridge just below it.

### Mountain Sickness

Lack of oxygen at high altitudes on the ground will have the same effect as lack of oxygen in a plane, except that the effect is intensified by physical exertion. Set a slow pace and make frequent short stops. Altitude or mountain sickness will be intensified by heavy exertion or by chilling, drinking cold water, or eating snow when you are tired and hot. An intense headache, weakness, and nausea are symptoms. Descent to lower altitudes and rest will effect a cure.

### Climbing Trees

If you want to go up a palm tree after coconuts, do it native-style. Make a small loop from a rope of braided palm fibers or vines, and slip it around your ankles. Then grasp the trunk of the tree with your hands and climb. Hold with your hands as you draw up your feet, then straighten your body, using the friction of the rope and your feet against the tree to keep yourself from slipping. Another method is to loop the rope around the tree and the ankles. As you pull yourself up, the loop lifts with your feet and then binds on the tree.

FIG. 42. Use Low Limbs

As for tree climbing in general, remember to test all limbs before you put your weight on them; don't try to shinny up a tree so big that you can't reach around it or so high you'll be exhausted and fall before reaching the first branch. Dead limbs are notoriously untrustworthy and *any* limb is strongest next to the trunk. You can get badly burned from attempting to climb with little or no clothing. Seldom trust your entire weight on one limb. Distribute it in two or three places. Be careful in climbing wet trees. When climbing large trees, utilize low-hanging branches, smaller trees and vines.

## CHAPTER III

# Water

Water is the most important single factor in determining survival. Without it, the presence or absence of food is of little importance. You can survive many days without food if you have water.

Under average conditions an individual needs at least a quart of water a day, but the amount essential under widely varying conditions of weather, climate and surroundings may be a great deal more or less. A man who knows how to use water intelligently may come through in reasonably good condition with a supply on which another man might die of thirst.

If you are extremely thirsty, sip slowly and don't take an excessive amount of water. Likewise, if you are hot from sun or from exercise, avoid drinking

FIG. 43. You Can Safely Drink from Streams Whose Upstream Portions or Sources Are Devoid of Human Habitations

cold water, or an excessive amount of water. If only cold water, snow, or ice is available, warm it in the mouth before swallowing.

If water is scarce, and you are exercising you will lose less through sweating if you drink a small amount at fairly frequent intervals than by taking a lot at a time. However, when the body is dehydrated there seems to be little difference.

### FINDING WATER

The water table is the surface below which the rocks of the earth are saturated with water. Its level tends to follow the contours of the land surface,

FIG. 44. Water Table

rising somewhat beneath hills, and in some places intersecting the surface to form springs and seepage areas or to merge with streams, swamps, lakes and oceans.

Water lying below the water table is termed ground water and in general is pure. Water lying above the table is runoff water and is much more likely to be contaminated. Water is an excellent germ-carrier and is almost always polluted near human habitations, particularly in the tropics. In inhabited areas it should be boiled. Streams, rivers and lakes usually are supplied by both ground and runoff water. Water from large lakes is generally safe if taken some distance from human habitation.

While running water tends to purify itself, it is not necessarily pure, nor is still water necessarily impure. A stagnant hole in the wilderness far from human habitation may be safe for drinking, and a running stream near a native village extremely dangerous. Water in swamps, bogs, and in pockets on the forest floor may be acid and dark from decaying vegetation, but it is not impure unless there is some outside source of pollution. Of course it should always be purified if it is near any human habitation.

A spring issuing from a rock usually is safe. Rain water is pure. *When looking for water remember that the water table is usually close to the surface and can be reached with little digging in low forested areas, along the sea-shore, and in the flood plains of large rivers.*

### Along the Seashore

Rain water absorbed by the ground gradually seeps seaward, meeting the salt water at the shore. Drinking water usually can be obtained along the seashore by scooping out holes in the beach at low tide, or by digging a shallow well some distance from the shore. Water obtained away from the shore is generally fresher, but more labor is required in getting it. The best spot for digging is in a low basin where drainage from the land is concentrated.

Fresh water will be found first when you dig since it is lighter than salt water.

Water from any hole dug near the sea is apt to be brackish, but is safe to drink as it is found. Water too brackish to drink frequently can be made palatable by running it through a sand filter several times. Brackish water, although salty in taste, doesn't have a high enough salt concentration to be harmful. *Drinking sea water in any quantity when the body is dehydrated is extremely dangerous. The concentration of sodium and magnesium salts in it is so high that fluid must be drawn from the body to eliminate the salts, and eventually the kidneys cease to function.*

### Desert or Arid Lands

*In all arid parts of the world there are numerous indicators of the presence of water.*

These include converging game trails, the presence and direction of flight of some birds, and the presence of certain plants.

Pigeons or parrots are always within reach of water. They may feed in the desert, but they will fly to water in the late morning and late afternoon. Water can be found by following their direction of flight. This rule may be of use in places as widely separated as our own Southwest, in Australia, and in desert regions of Asia and Africa. The sand grouse of arid parts of Asia are pigeon-like birds that fly many miles to congregate at water holes, for they must drink

at least once a day. Crested larks and desert species of weaver birds and coursers may fly regularly to nearby water in the evening. Presence of diamond or zebra birds in the dry country of Australia is an almost infallible indication of

FIG. 45. Sand Grouse

the nearness of water. Many desert bats visit water regularly at the beginning of their evening flight.

*Some plants grow only where ground water is close to the surface.* Salt grass, rushes, sedges, cattails, greasewood, willows and elderberry are examples with which you may be familiar. Desert palms usually indicate surface water.

In dry regions, dig for water where vegetation appears to be greener or larger or markedly different from surrounding types, or where the sand is damp in dry river beds or other low areas. Brackish desert water should be filtered using soil a foot or so below the surface. The surface soil may itself be saturated with salts.

*Dew can be collected in useful quantities during a clear night.* Go abroad before daylight and gather it in a cup by tapping vegetation, or sponge it up with a handful of soft grass or a cloth. Australian natives sometimes mop up as much as a quart an hour in this way.

As a last resort, water may be obtained by breaking off a young desert tree at the base, and then removing the top. Turn the broken trunk upside down, and collect water from the drippings. (Methods of getting water from other plants are discussed on pages 44 through 48.

### **Mountains**

On a clear day, mountain snow can be melted by placing a shallow container on a sunny exposure out of the wind. Apparently dry mountain stream beds often will contain water beneath the gravel stream bottom. Put your ear to the ground and listen for the trickle.

### **Finding Water in Cold Weather**

In cold weather, springs and spring-fed streams remain open when other water courses are frozen.

Water can be obtained by cutting through the ice of a stream or lake. To obtain water by melting, use fresh ice or granular snow in preference to new spongy snow, as a smaller bulk will make more water and take less fuel and time. Eating snow and ice will quench thirst, but tends to chill the stomach and reduce body temperature.

In the Arctic Sea the most widely available water source is *old* salt-water ice, which can be distinguished from salt-ice by its bluish color and smooth, rounded corners. (Salt ice is grey and milky.) In summer, depressions on icebergs and floes contain fresh water. In bays or inlets protected from wind and current, water from melting snow and ice accumulates on the surface of the denser salt water and may remain fresh and unmixed with ocean water for long periods.

## WATER FROM PLANTS

*Sap is chiefly water and from many plants it is both fit to drink and readily available.*

In an emergency, a water-yielding plant may save your life, or save valuable time by eliminating the necessity of purifying water from questionable sources. Some tropical lianas and palms have a steady flow of water in their stems. The fruits, growing tips, leaves, stems and buds of many plants contain small quantities of water.

### *Water from Succulent Plant Tissues*

Many desert and other plants store water in their fleshy leaves or stems. In an emergency, such sources should be tried anywhere you happen to be.

The barrel cactus of the southwestern United States is well known as a source of water. Cut off the top of the plant, mash the pulp within against the inner sides, and the water will ooze out and collect in the bowl. The fruits and roasted pads or stems of very young prickly pears taste somewhat like asparagus and will help quench thirst.

### *Water from the Roots of Desert Plants*

Water may be obtained from the roots of some desert plants that have their roots near the surface. The "water trees" of arid Australia are a part of the

FIG. 46. Getting Water from a Barrel Cactus

FIG. 47. Water from Grapevine

mallee scrub, one of the largest and most distinctive plant formations of Southern Australia. Roots of these "water trees" run out 40 to 80 feet at a depth of two to nine inches under the surface.

To get water from them, locate the root four or five feet from the tree trunk, pry it out of the ground, cut it into two- or three-foot lengths, and peel off the bark. Drain each section into a container, or suck out the water. One large mallee root usually will supply the water needs of two or three thirsty men.

Trees growing in hollows between ridges will have the most water, and roots one to two inches thick are ideal in size. Water can be carried in these roots by plugging one end with clay.

*Water from the roots of all water producing plants is obtained in a manner similar to that described above.* These plants include the Australian needle bush, desert oak, bottle tree, bloodwood, and several varieties of *Acacia*. The "water tree" or vine of Africa and South America is utilized in the same way.

#### **Water from Vines, Stems, and Fruits**

**Vines.**—Many large vines or lianas found in tropic rain forests contain a pure watery sap with a slightly acid flavor. Since not all of them will yield water, and the fluid from some is more palatable than others, it will be

desirable for you to experiment with various species. Try any grapevine. The method of tapping them is the same for all:

Reach as high as you can and cut a deep notch in the vine or cut it off, keeping the severed end elevated. Then cut the vine close to the ground; this

FIG. 48. Make the Second Cut below the First One

should give you a water tube six to seven feet long. When water stops dripping from the lower end, cut another section off the top and more water will drain out. If the bottom of the vine is cut first, part or all of the water will be lost, as the water will ascend. (Grape vines found in the United States will yield water in this manner in the summer and fall.)

Many species of rattan palms produce good drinking water. They are vine-

like palms with long, slender, segmented stems and sharp, downward curving thorns, and are widespread in tropical jungles and virgin forests.

*Palms*.—A drinkable sugary sap can be obtained in quantities from the buri, nipa, coconut, sugar and other palms. To start coconut sap flowing, bend the flower stalk downward and cut off the tip. Every 12 to 24 hours cut off a thin slice to renew the flow, which may reach a quart or more daily. The flow of sap can also be started by first bruising a lower frond and then pulling it down so the tree will "bleed" at the injury. The sap will run down the trough-like frond and can easily be collected.

On any one coconut palm, the nuts will be in varying stages of maturity. Contrary to your usual experience, the green nuts are the best. They are more easily opened with a knife or machete, have more fluid, and the fluid can be taken in quantity without harmful effects. The delicious juice of the ripened coconut will act as a violent physic if taken in quantities of more than three or four cups daily.

To get to the edible part of a coconut, slice off the stemless end of the outer husk to form a point, then cut off the point so as to sever the end of the inside shell. To husk a coconut without a knife, drive it on a sharp stick stuck in the ground, then crack the hard inner shell.

*Banana and bamboo*.—The slightly astringent water from the trunk of young banana trees is suitable for drinking. Water also can be obtained from the stems of some bamboos. (Shake them to see if water is inside.)

#### *Plants That Catch and Hold Water*

*Many plants catch and store rain water in natural receptacles or decayed hollows.*

The traveler's tree of Madagascar and Reunion has a cup-like sheath at the base of its vertical, fern-like leaves, in which quantities of drinkable water collect. Water can be obtained from both the leaf bases and roots of the umbrella tree of western tropical Africa.

The bottle-like trunk of the baobab tree of the sandy plains of northern Australia and Africa in the wet season collects water which frequently is found fresh and clear after weeks of dry weather.

FIG. 49. Bromelias

The air plants which affix themselves to jungle trees are good water reservoirs. Leaves of the pineapple-like Bromelias in particular form regular basins which may catch and hold several pints of rain water.

### MUDDY, STAGNANT AND POLLUTED WATER

It is often necessary to use muddy, stagnant, or polluted water. Water polluted by mud or animals is unpleasant *but harmless if it is boiled.*

FIG. 50. Bamboo-sand  
Water Filter

FIG. 51. Reed  
Water Filter

Muddy water can be partially cleared by allowing it to stand overnight. It can be cleared more quickly, however, by passing it through a filter such as a sand-filled cloth, a length of bamboo filled with sand and clogged with grass or clothing to keep the sand in, or by using a grass or reed cone. For the latter, tie a handful of grass in the shape of a cone, six to eight inches long. Dip the cone into the puddle, then flick it upward and out. Water will trickle down through the small end of the cone.

Split cactus or *Opuntia* stems or "pads" placed in muddy water tend to clear it by gathering much of the sediment on their gelatinous tissues. These cacti are natives to the Americas but are also found in North Africa, Australia and India. (The best method of water clarification is by the use of ammonium alum, which forms a precipitate and settles to the bottom.)

Water with a disagreeable odor should be boiled and the odor neutralized by adding charcoal and ash from the fire.

*Water that has merely had the sediment cleared out of it is not purified.*

To be safe it must be boiled at least three minutes or longer. Halazone tablets, or three or four drops of iodine to a quart of water will help to

purify unboiled water. Let it stand for a half hour before drinking. If there is a slight chlorine smell, the water is safe to drink.

### DANGERS OF DRINKING IMPURE WATER

*Don't try to short-cut on water purification.* Water-borne diseases are one of the worst hazards of tropical and subtropical countries, particularly where there are native populations. An "untouched" wilderness is relatively safe.

If you boil or chemically purify all drinking water thoroughly you will reduce greatly the dangers of contracting dysentery, cholera, typhoid fever and some of the parasitic infections.

#### **Dysentery**

Dysentery is the most common of the water-borne diseases. The most noticeable symptoms of both the amoebic and bacillary dysentery are severe and persistent diarrhea accompanied by mucus and blood mixed with the stools. There is fever and general weakness. If drugs are available, first try bismuth subnitrate (one teaspoon every few hours in a little water until disturbance stops). If this does not help, take 1 capsule of carbosone (0.25 gm.) after each meal for five days and see a doctor as soon as possible.

#### **Cholera and Typhoid**

You will be given inoculations as a preventive against contracting these two diseases, but nevertheless don't take chances when they are prevalent.

#### **Flukes and Worms**

Blood flukes that parasitize man and cause painful and often fatal diseases can be picked up through drinking sluggish, contaminated water in tropical regions.

Some small crustaceans act as intermediate hosts to human parasites such as the guinea worm, and are swallowed in drinking water. The guinea worm larvae penetrate the walls of the intestines and migrate through the tissues, lodging finally just beneath the skin. They produce blister-like lesions on the lower extremities through which the young worms are discharged. If the

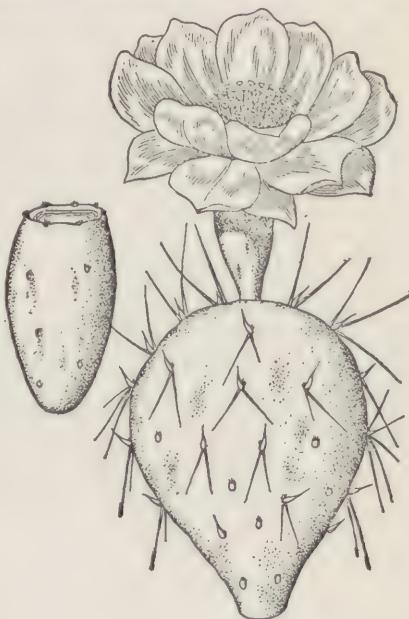

FIG. 52. Cactus (Opuntia)

361083

APR 5 '44

victim submerges himself in water, the worm protrudes its tail to eject eggs or larvae. Then it can be pinched and cautiously drawn out. Guinea worm disease is found in large areas of Africa, India, Persia, Turkestan, West Indies and Northern South America.

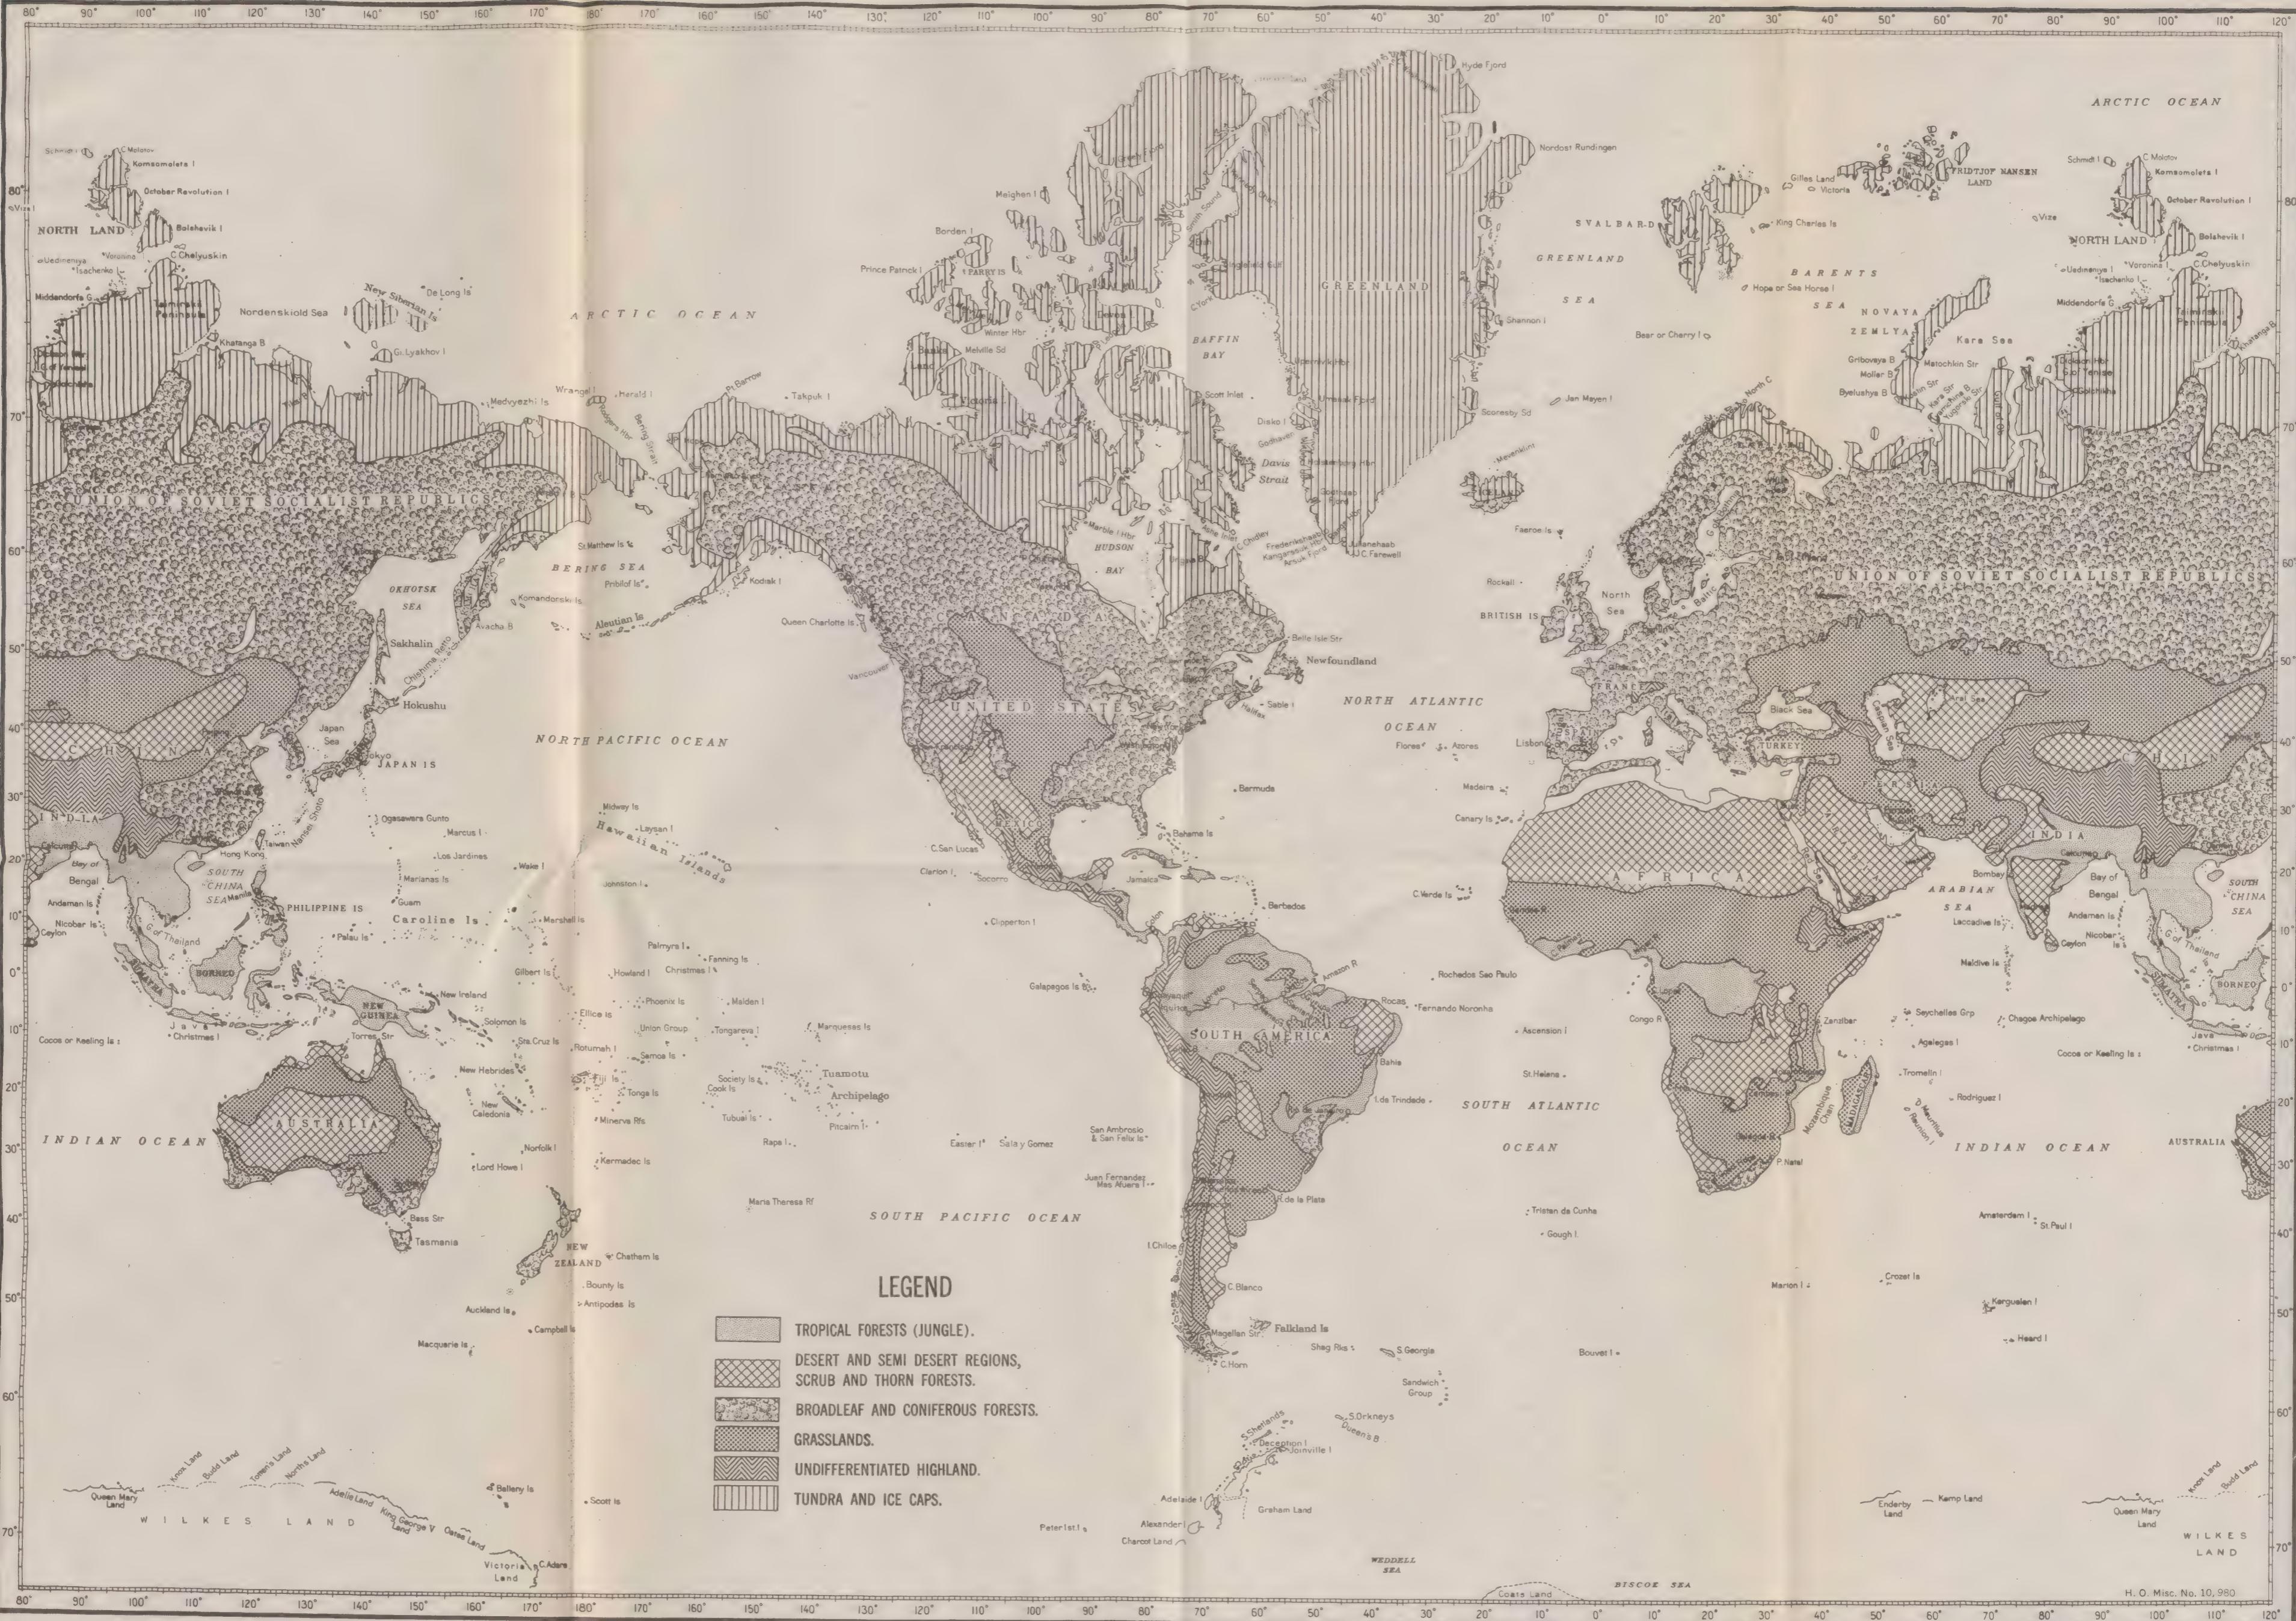

Prophylaxis consists in drinking only boiled water.

### *Leeches*

In some areas, particularly in Africa, small leeches may be swallowed with the drinking water. They will attach themselves to the throat and nasal passages, sucking blood and creating wounds which will continue to bleed after the leeches shift to new positions. The leeches can be removed with forceps or by sniffing highly concentrated salt water.

The list of tropical diseases is impressive, but so is the list of those you might acquire at home if you didn't take normal precautions against them. You have been immunized against some of them, and can greatly reduce the chance of your getting any others by following recommended safety practices, and using medical facilities whenever they are available.

# WORLD DISTRIBUTION OF THE PRINCIPAL VEGETATIVE REGIONS

## CHAPTER IV

# Wild Plant Food

Food follows water in the order of its importance in survival, and plants will be one of your most valuable food sources. To use them intelligently in an emergency you must have some practical knowledge of what they look like and where they grow.

### RECOGNITION AND USE OF PLANTS

There are thousands of edible plants distributed throughout the world. Descriptions and pictures will help you identify them, but *the best way to familiarize yourself with the appearance and use of edible plants is to have someone point them out to you. Each time you are shown a plant, make a mental note of the kind of place (the habitat) in which you find it.* Without any particular effort you may soon find that you know just where to look for the best food plants of a region; for coconuts, breadfruit and plantains in the Tropics; for cranberries, salmon berries and crowberries in the Arctic.

Mastery of a few general facts and principles that you can learn beforehand will help you to find and recognize food plants in any part of the world.

Many groups of plants found at home are widespread throughout the world. Some of those found in North America also grow in the Philippines, in Malaya, Africa, India, China, Europe, the Arctic and other remote places. Although the different kinds or species which compose a group may be limited in distribution and habitat and may vary in minor details, all are similar in general appearance. When a plant appears to be familiar, use it as you would that kind of plant at home. The persimmons of the Philippines or China, for example, differ somewhat from our American ones, but they have characteristics by which you will recognize them as persimmons. (See Figures 53 and 95.)

Almost everyone has picked and eaten

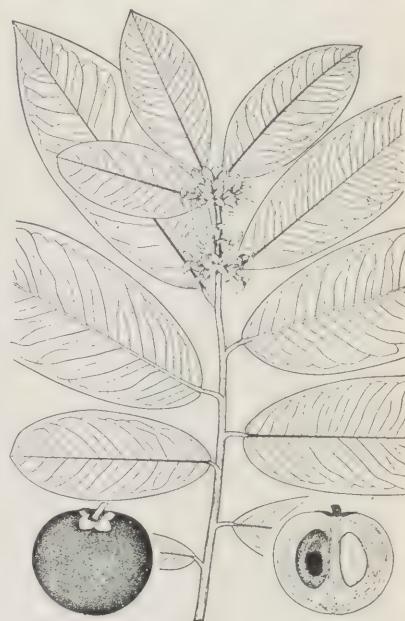

FIG. 53. Philippine Persimmon  
(*Diospyros*)

raspberries or blackberries from thorny brambles near the edges of woods, fences, roads and trails. They will look the same when found in the Philippines, Pacific Islands, Africa, Australia, Siberia, Alaska, the Arctic, and other areas.

Most Americans have picked and eaten the round, dark blueberries, that grow on low bushes in areas where the soil is acid, such as the borders of bogs and swamps or sandy mountain or coastal plain areas. Blueberries and their close relatives are found in practically all parts of the world except Australia. (See Figures 54 and 101.)

In Temperate zones fruit of some kind can be found the year around, though most of them are available only in summer or fall.

In the Tropics some plants flower and fruit continuously, and some fruits are available at all times.

Arctic fruits ripen only during a short summer period.

Edible portions of plants vary greatly in their food value. A diet of leaves alone is at best like eating only spinach. Select young, tender leaves in preference to old ones, and boil them. Change the water if they are bitter.

Buds are still more nourishing. The stems of some plants are excellent, furnishing starch, sugar, oils and greens. (See pages 72-74.)

### **Roots and Other Underground Parts**

Many plants store food (starch) in underground parts. This is especially true of aquatic plants. Tubers are a source of food in all parts of the world and are often available throughout the year. In cold climates when plant food appears completely absent, bulbs and roots can be found by digging where the dried plant stalks remain. (See pages 63-67.)

### **FERNS**

The roots and young curled fronds of many ferns are edible and none are known to be poisonous. The food value is not great, but it will help sustain life. The brake fern is eaten by natives all over the world. A fern called Pakó furnishes edible young fronds which are eaten either raw or cooked by Philippine natives. It grows in wet ground, on gravel bars, and along the banks of streams.

FIG. 54. Philippine Blueberry (Vaccinium)

FIG. 55. Gathering Tubers of Solomon's Seal

FIG. 56. Pulling Up Cattail Roots

FIG. 57. High Climbing Fern  
(*Stenochlaena palustris*)

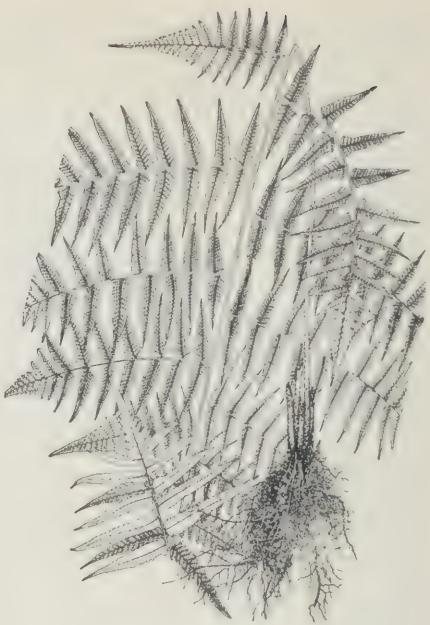

FIG. 58. Pakó Fern  
(*Athyrium esculentum*)

FIG. 59. Swamp Fern (*Ceratopteris*)

FIG. 60. Tree Fern (*Cyathea*)

The young shoots of a high climbing fern are eaten cooked or raw by natives of the South Pacific area and India. This fern grows in thickets in the vicinity of brackish or salt water. The young leaves and terminal buds of tree ferns are edible. These huge ferns may be 20 or more feet high and are found in wet jungle areas. The succulent foliage of the common swamp fern is boiled and eaten as a vegetable. It is found either floating or attached to the soil in shallow, still, or slightly moving fresh water in the subtropical and tropical regions of Asia, Africa, America and Australasia.

### WIDELY DISTRIBUTED NUTS

*Edible nuts are the most sustaining of all raw forest foods and are found throughout the world. Many American nut trees are found throughout the North Temperate zone and closely related trees of similar appearance grow in the Tropic and South Temperate zones. Familiarity with some of the common North American nut trees will help you to recognize and locate nut-bearing trees in other regions. Pine trees, for example, grow throughout the North Temperate zone and seeds from the cones of many of them are edible and very sustaining. They are a principle article in the winter diet of the Indians of our Southwest and of the peasants in remote regions of Siberia.*

The single leaf pine, the sugar pine, the limber pine, the nut or pinon pine and the Coulter pine of our American West produce cones containing seeds or nuts that are both tasty and nourishing. The seeds from the Nepal nut pine and the Emodi pine of the Himalayas, the Swiss stone pine of Europe and Asia, the Korean pine of China, Japan, Korea and Kamchatka, all produce edible nuts. It is not necessary to be able to differentiate between pines. Shake or break seeds out of the cones and try eating them.

Recognizable members of the pine family bearing edible seeds also grow in the tropical and South Temperate zones. Nuts from the Araucarias of Australia and New Zealand, Brazil, Chile, Norfolk Island and New Caledonia furnish excellent food. These are lofty evergreens bearing globular cones containing large chestnut-like nuts which may be eaten raw just before ripening, or may be either boiled or roasted. (See Figure 62.)

FIG. 61. Single Leaf Nut Pine  
(*Pinus monophylla*)

Nut-producing members of the beech family, represented in North America by the oaks, beechnuts and chestnuts, are found in many parts of the world.

Chestnuts, hazelnuts and walnuts are found in North America, the West Indies, Europe and all of Asia including the Philippines and the East Indies.

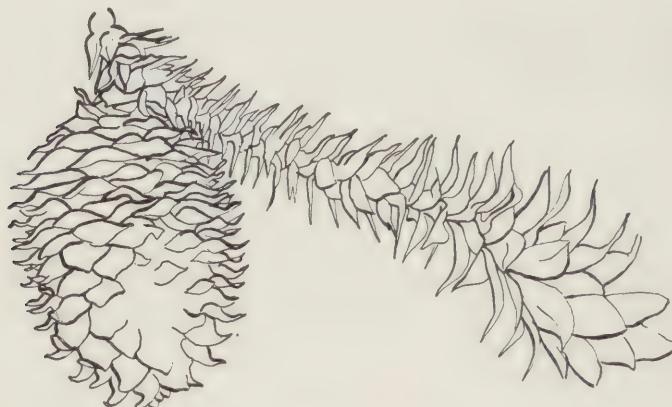

FIG. 62. Bunya Pine (*Araucaria*)

### SOME NUT TREES WITH WIDE DISTRIBUTION

#### Beech.

Characteristics: Large forest trees producing triangular nuts. Bark smooth varying from light to dark gray.

Distribution: North temperate zone.

Eaten: Raw.

FIG. 63. Beech Nut (*Fagus americana*)

#### Oak.

Characteristics: Trees and shrubs producing acorns; leaves either evergreen or deciduous (falling).

Distribution: Edible species found in Java, India, China, Mexico, North and South America, northern Africa, Mediterranean area.

FIG. 64. Oak (*Quercus alba*)

Eaten:

Sweet acorns raw. Bitter acorns boiled in changes of water, or dried and roasted; or ground into flour, soaked in water, and baked or roasted in cakes.

FIG. 65. Chinquapin  
(*Castanea pumila*)

### Chestnut and Chinquapin.

Characteristics: Oak-like trees or shrubs containing nuts in burrs lined with soft, leathery covering.

Distribution: North America, West Indies, Europe, Asia including Philippines and East Indies.

Eaten: Raw, boiled, roasted.

FIG. 66. Bush chinquapin  
(*Castanopsis sempervirens*)

FIG. 67. Walnut  
(*Juglans nigra*)

### Hazelnut.

Characteristics: Small trees or bushes with nuts in clusters and covered by leaf-like husk.

Distribution: See chestnut and chinquapin.

Eaten: Raw.

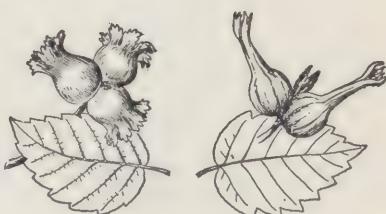

FIG. 68. Hazelnut (*Corylus americana*)  
(*Corylus rostrata*)

## NUTS RESTRICTED IN DISTRIBUTION

Many nut trees, relatively restricted in range as are the hickory nuts and pecans of North America, will furnish food in certain areas of the world.

## Australian nut trees.

Characteristics: Grow 25 to 30 feet tall, hard-shelled nuts grow in bunches and encased in husks like hickory nuts.

Distribution: Australian jungles.

Eaten: Raw.

## Panama nut tree.

Characteristics: Immense forest tree with thick trunk of buttressed roots and huge crown with large hand-shaped leaves. Fruits in five pods containing black, peanut-like seeds, covered with irritating hairs.

Distribution: Central and South America, with other species in various parts of the Tropics.

Eaten: Raw or roasted.

## African walnut or gabon.

Characteristics: Desert nut resembling a walnut.

Distribution: Liberia and adjacent regions.

Eaten: Raw, boiled, roasted.

## Pili nut.

Characteristics: Large forest trees. Hard inner nuts are triangular in cross section and pointed at each end.

Distribution: Philippines, other Pacific islands, and Malaya.

Eaten: Raw, but much improved by roasting.

FIG. 70. Pili Nut (*Canarium*)

### Brazil nut.

Characteristics: Grows in immense forests with trees attaining 150 feet in height and 4 feet in diameter.

Distribution: Brazil, the Guianas, Venezuela.

Eaten: Raw.

### GRASSES

By far the largest part of human food comes from such grasses as oats, wheat, corn, and rice; and the seeds of all grasses are edible. Grasses are distinguished by their joined and usually hollow stems.

FIG. 72. All Grass Seeds Are Edible

FIG. 71. Brazil Nut (*Bertholletia excelsa*)

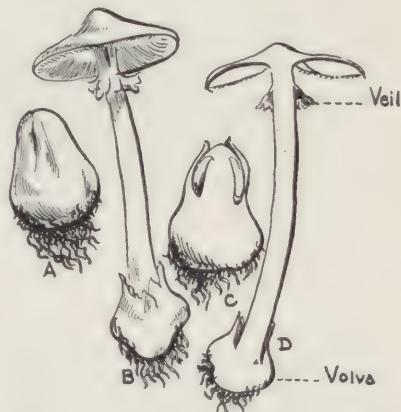

FIG. 73. Amanita Mushroom (Poisonous). a. Young Amanita; c. Cross Section of Young Amanita; b, d. Mature Mushroom.

Wild rice, one of the staple foods of the American Indians, is distributed widely, with both wild and cultivated rice particularly abundant throughout the tropics. Many kinds of sorghums and millets are found in the tropics. Wild oats grow in Europe, Asia, North America, Australia, and the upland regions of South America. Their grains can be eaten raw, parched, or pounded into flour and roasted. At long intervals bamboo produces edible seeds, and the young shoots of most varieties may be eaten safely.

### MUSHROOMS

Many mushrooms are edible and may furnish a source of food, particularly in temperate regions; but no species should be tried unless you are sure of its

*identity, for some species are deadly poisonous.* The most widespread among the dangerously poisonous mushrooms are the Amanitas which have a frill or ring (veil) around the upper part of the stem, a bag (volva) at the bottom, and a white spore deposit which drops out of the gills. Don't try eating any mushroom that possesses these three characteristics. Amanitas almost always grow on the ground in the woods or shade. No poisonous mushrooms have ever been reported from the Northwest Canadian territories, and the only poisonous mushroom in Alaska is the Amanita. (See Figure 73.)

FIG. 74. Puffball

FIG. 75. Morel  
Mushroom

Puffballs are more or less globular bodies that develop their spores inside and have a solid white interior when young. *All are edible when fresh.* An inexperienced person might at first mistake them for the young Amanita, but he can distinguish them readily by cutting them open. The young Amanita has all the characteristics of a mature mushroom, though reduced and compressed, while the puffballs do not. Avoid eating all fungi in the button or unexpanded stage. *Morel mushrooms are easily recognized and all are edible.*

### BEVERAGES FROM PLANTS

*Some plants which have little food value can be used for making refreshing beverages.* The bark from sassafras roots, spicebushes, black birch, sumach berries, the leaves of wintergreen, Laborador tea, spruce, hemlock, many of the mints, and other plants produce palatable drinks when steeped or boiled.

### BARK AS FOOD

*The inner barks from numerous trees can be eaten raw or cooked.* In famine areas people make bread from flour derived from the bark of trees. The thin,

green, outer bark and white, innermost bark are those normally useable for food since brown bark ordinarily contains too much tannin. Among trees whose bark is used as sources of food are the poplars (including the cottonwoods and aspens) birches, willows, and the inner bark of a few species of pine, including the Scotch pine of northern Europe and Asia and the lodgepole or shore pine of western North America. Outer bark of these pines is scraped away and the inner bark stripped from the trunk and eaten fresh, dried or cooked. It is most palatable when newly formed in the spring.

### POISONOUS AND IRRITATING SUBSTANCES

Some plants may be eaten only after poisonous or irritating substances are removed. Among these are a large group known as the Aroids, of which the taro root, a staple food of the Polynesians, is a good example. It is pungent and bitter when raw, but perfectly palatable after cooking. Jack-in-the-pulpit, found in the United States, and Badu or Coco of the West Indies or Central America are edible when the roots are cooked, but even prolonged cooking may not make elephant ear or skunk cabbage edible.

When eaten raw, the needle-shaped crystals of calcium oxylate puncture the tongue and cause a stinging sensation. Drying (roasting) so rearranges the crystals of some of them as to make them harmless. One taste of skunk cabbage or jack-in-the-pulpit will enable you to recognize this irritating principle when found in other plants.

Roots of the bitter manioc of South America contain small quantities of the poison, hydrocyanic acid. The root is prepared as food by crushing, pressing and washing the juice containing the poison and then heating to drive out the last traces.

Some fruits and seeds are poisonous at certain stages of growth but not at others; while many plants contain some edible and some poisonous parts. An example is the poke weed, whose young shoots and leaves are edible, but whose root is poisonous.

### SOME COMMON EDIBLE WILD PLANTS OF THE UNITED STATES FOUND ELSEWHERE IN THE WORLD

The following groups or genera of food plants are widely distributed. Some contain numerous edible species. By learning a few plants from each group you will be better able to recognize and use the same or related species in any area of the world. Instead of attempting to learn them all in a short time, learn a few well, adding to the list from time to time.

FIG. 76. Digging Arrowhead Tubers

Along all streams, swamps or open water areas hunt for plant food by digging for roots and tubers. The best time for gathering arrowhead tubers in the United States is the fall of the year. Note the arrow-shaped leaves and pile of bulbs in the foreground. Roots that angle or go straight down are more likely to terminate in a tuber than are the shallow lateral roots. (See Arrowhead, page 65.)

*Roots and Other Underground Parts***Wild onion.**

Found: Small plants, North America, Asia, Europe. Year round but difficult to locate in winter.

Eaten: Bulb, boiled or raw.

FIG. 77. Wild Onion  
(*Allium cernuum*)

FIG. 78. Spring Beauty  
(*Claytonia virginica*)

**Spring beauty.**

Found: Small plants, Africa, Europe, Australia, southern Asia, North America. Year round but difficult to find in winter. Common in moist woods of North America.

Eaten: Bulb raw or cooked.

Note: Leaves only of some species are eaten.

**Nut grass.**

Found: Sedge, worldwide, common in open ground and along river banks. Available in U.S. during summer, fall, winter.

Eaten: Small hard nut-like tubers, raw or cooked.

FIG. 78. Nut Grass  
(*Cyperus esculentus*)

FIG. 80. Water Chestnut  
(*Eleocharis tuberosa*)

### Water chestnut.

Found: Many parts of world, particularly in southern Asia and Pacific Islands. Plant grows wild in some fresh water swamps of U.S.

Eaten: Tubers, raw or cooked.

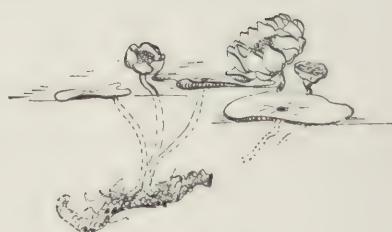

FIG. 81. Water Lilies (*Nymphaea, Nelumbo*)

FIG. 82. Wild Potato  
(*Ipomoea pandurata*)

### Wild and sweet potatoes.

Found: Trailing plants, in all warm climates of the world.

Eaten: Large tuberous roots, chiefly cooked (baked, roasted, boiled.) Leaves and stems as greens.

**Solomon's seal.**

Found: Small plants, North America, Europe, northern Asia, Jamaica. Available U.S. in spring or summer.

Eaten: Fleshy roots boiled or roasted taste like parsnips. Young shoots also edible.

FIG. 83. Solomon's seal (*Polygonatum commutatum*)

FIG. 84. Brake Fern (*Pteris aquilina*)

**Brake fern.**

Found: Nearly all temperate and tropical regions, year around.

Eaten: Preferably roast and chew starch out of roots, raw if necessary. Stalks and coiled young fronds as greens, in U.S. in spring or summer, but first remove wool-like covering.

**Arrowhead.**

Found: Small plants, North America, Europe, Asia. In U.S. year around. Follow thread-like root down to the bulb. Grows in wet ground and shallow water.

Eaten: Boil or roast. Tastes like a potato.

FIG. 85. Arrowhead (*Sagittaria latifolia*)

FIG. 86. Bulrush (*Scirpus validus*)

### Bulrush.

Found: Tall plant, North America, Africa, Australia, East Indies, Malaya. In U.S. year round, in wet and swampy areas.

Eaten: Roots and white stem base, raw or cooked.

FIG. 87. Wild Potato (*Solanum Jamesii*)

FIG. 88. Cattail (*Typha latifolia*)

### Cattail.

Found: Tall plants, Europe, northern Asia, North America, Africa, Australia and some Pacific islands. Available year round, always near water.

Eaten: Bake or roast roots and chew out starch, discarding fiber, may also be eaten raw. White portions of the new shoots and the flowering spike edible (before blooming.)

**Wild Rice.**

Found: Tall grasses, North America and Asia along swampy streams, rivers, bays. Base of stems and root shoots in U.S. best in spring or summer, grain in late summer and fall.

Eaten: Lower stem and root shoots are sweet. Remove tough covering and chew central portion. Grain is excellent.

FIG. 89. Wild Rice  
(*Zizania aquatica*)

**FRUITS AND BERRIES**

FIG. 90. Juneberry (*Amelanchier canadensis*)

**Juneberry.**

Found: Small trees, North America, northern Asia, Europe, in forest and mountain areas. In U.S. summer and early fall.

Eaten: Small purplish fruit, fresh or dried.

**Papaw.**

Found: Tree, North American papaw in fall. Along streams. Related custard apple family found throughout tropics.

Eaten: Banana-like tasting fruit, skinned and eaten raw. Black or yellowish-green when ripe.

FIG. 91. American Papaw  
(*Asimina triloba*)

FIG. 92. Wild Grapes in Other Parts of the World Will Look Like Those at Home

**Hackberry.**

Found: Trees, North America, temperate Asia, northern India, Europe, either in arid or moist habitats. U.S. in fall, winter.

Eaten: Raw or cooked.

FIG. 93. Hackberry (*Celtis occidentalis*)

FIG. 94. Hawthorn (*Crataegus*)

**Hawthorn.**

Found: Bushes, open waste lands of temperate Asia, Africa, Europe, North America, Mexico, East Indies. U.S. in fall and winter. In winter, look on ground beneath the bushes.

Eaten: Tiny red or yellow apples, raw or cooked.

FIG. 95. Persimmon (*Diospyros virginiana*)

**Persimmon.**

Found: Trees, North America, South America, Asia, Africa, Australia, Pacific islands.

Eaten: Ripe (soft) fruits only, eaten raw or cooked.

FIG. 96. Mulberry (*Morus*)**Mulberry.**

Found: Trees, all north temperate regions and subtropics, U.S. in summer.

Eaten: Raw or cooked.

FIG. 97. Wild Cherry (*Prunus virginiana*)FIG. 98. Golden Currant (*Ribes aureum*)**Currants and Gooseberries.**

Found: Low sometimes prickly shrubs throughout the Americas and in Europe, Asia, North Africa, Australia and elsewhere.

Eaten: Berries raw or cooked.

**Blackberries and Raspberries.**

Found: Shrubs, nearly worldwide, U.S. in summer, in open land and forest margins.

Eaten: Raw or cooked.

FIG. 99. Wild Raspberry (*Rubus strigosus*)

FIG. 100. Elderberry (*Sambucus canadensis*)

**Blueberries and cranberries.**

Found: Shrubs, the arctic, north temperate and tropical areas. U.S. in summer and fall with some berries remaining through winter. Abundant in burned over areas of north.

Eaten: Raw or cooked.

FIG. 101. Blueberry (*Vaccinium angustifolium*)

### Grapes.

Found: Climbing vines, nearly worldwide, U.S. in fall and winter.

Eaten: Raw or cooked.

FIG. 102. Frost Grape (*Vitis bicolor*)

### LEAVES, STEMS AND SHOOTS

#### Burdock.

Found: Worldwide, particularly in open waste land. Stems available U.S. spring and summer.

Eaten: Tender leafstalks of this weed peeled and eaten raw or cooked as a green. Root is edible.

FIG. 103. Burdock (*Arctium Lappa*)

FIG. 104. Sorrel (*Oxalis violacea*)

#### Sorrel.

Found: Small plants, nearly worldwide.

Eaten: Leaves raw as a salad. Tubers of some species cooked.

**Goosefoot.**

Found: Weeds, all temperate and tropic regions, U.S. in spring and summer.

Eaten: Leaves cooked as greens, seeds toasted.

FIG. 105. Goosefoot (*Chenopodium album*)

FIG. 106. Plantain (*Plantago major*)

**Purslane.**

Found: Fleshy plant, worldwide. U.S. summer and fall.

Eaten: Fleshy leaves and stems boiled.

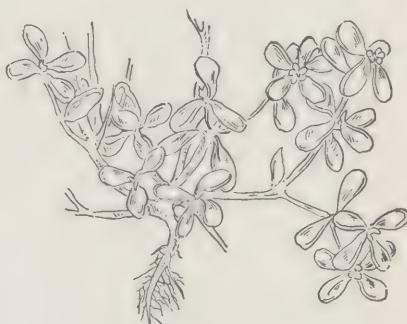

FIG. 107. Purslane (*Portulaca oleracea*)

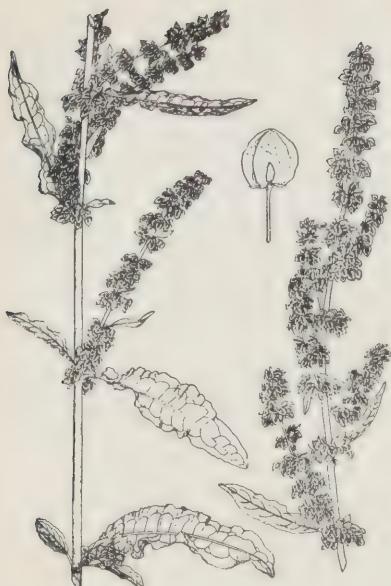

FIG. 108. Dock (*Rumex crispus*)

**Dock.**

Found:

Weeds, north and south temperate regions. U.S. spring and fall.

Eaten:

Young basal leaves boiled or raw.

**Dandelion.**

Found: Weeds, most of civilized world.

Eaten: Young leaves, cooked. Roots may be eaten raw.

FIG. 109. Dandelion (*Taraxacum officinale*)

## CHAPTER V

# Wild Animal Food

Animal food is any food not derived from plants. It may be in the form of fish, birds, mammals, crayfish, insects, mollusks and so on. It is in general more nourishing than wild plant food and often more available; thus a knowledge of the animals you can eat, where to look for them and how to catch them will increase your chance of surviving.

### FISH

*Learn to look upon bodies of fresh water as food reservoirs, and when lost or stranded in any type of country, try to strike a river or stream. Generally speaking, animal life is more abundant in the water than on land, it is concentrated in a more limited area, and quite often is easier to get. Your chance of surviving along a body of water is excellent. You can catch fish with crude equipment or with none at all if you know when, where and how to fish.*

FIG. 110. Fishing with a Bark Line

### When to Fish

Different species of fish feed at all times of the day and night. In any body of water many factors govern feeding activity; *but in general, early morning and late afternoon are the best times to fish with bait*. Fishing is usually good just before a storm breaks. Jumping minnows and rising fish are feeding signs.

### Where to Fish

FIG. 111. Catfish Caught on Makeshift Hook and Bark Line

Pick a good place to fish or your efforts are wasted. It is usually easier to locate fish in small shallow streams, than in large streams, lakes or rivers where they can find suitable habitats over a much wider area. Peer into the water away from the sun, or reflections will make it impossible to see fish.

In streams, fish usually congregate in pools and deep calm water. The heads of riffles, small rapids, the tail of a pool, eddies below rocks or logs, deep undercut banks, in the shade of overhanging bushes, wherever you see submerged logs and rocks—all are likely places to fish.

Fish the mouths of small tributary streams when the main rivers or streams are high or muddy. Fish seek shelter here at such times.

When streams are low and the weather is hot, fish congregate in the deepest pools and at places where cool underground water enters the main stream. At such times fish are much more likely to hide under rocks. (See *Fishing with Hands*, page 79.)

In the cool spring weather of temperate climates, fish keep to the shallow water that is warmed by the sun.

### Bait

Experiment with baits. Look for bait in the water, for this is the source of most fish food. Insects, crayfish, worms, meat of shellfish, wood grubs, immature forms of aquatic insects, small minnows and fish eggs are all good. So are the intestines, eyes, and flesh of other fish. Fruits are seldom good baits. After catching your first fish, open it and examine the stomach and intestines. See what it was feeding on and try to duplicate it. If it is crayfish, turn over rocks in the stream until you get one. Usually the rest of the fish will be feeding on the same food.

Make live bait appear to act natural and try to conceal the hook. Don't let

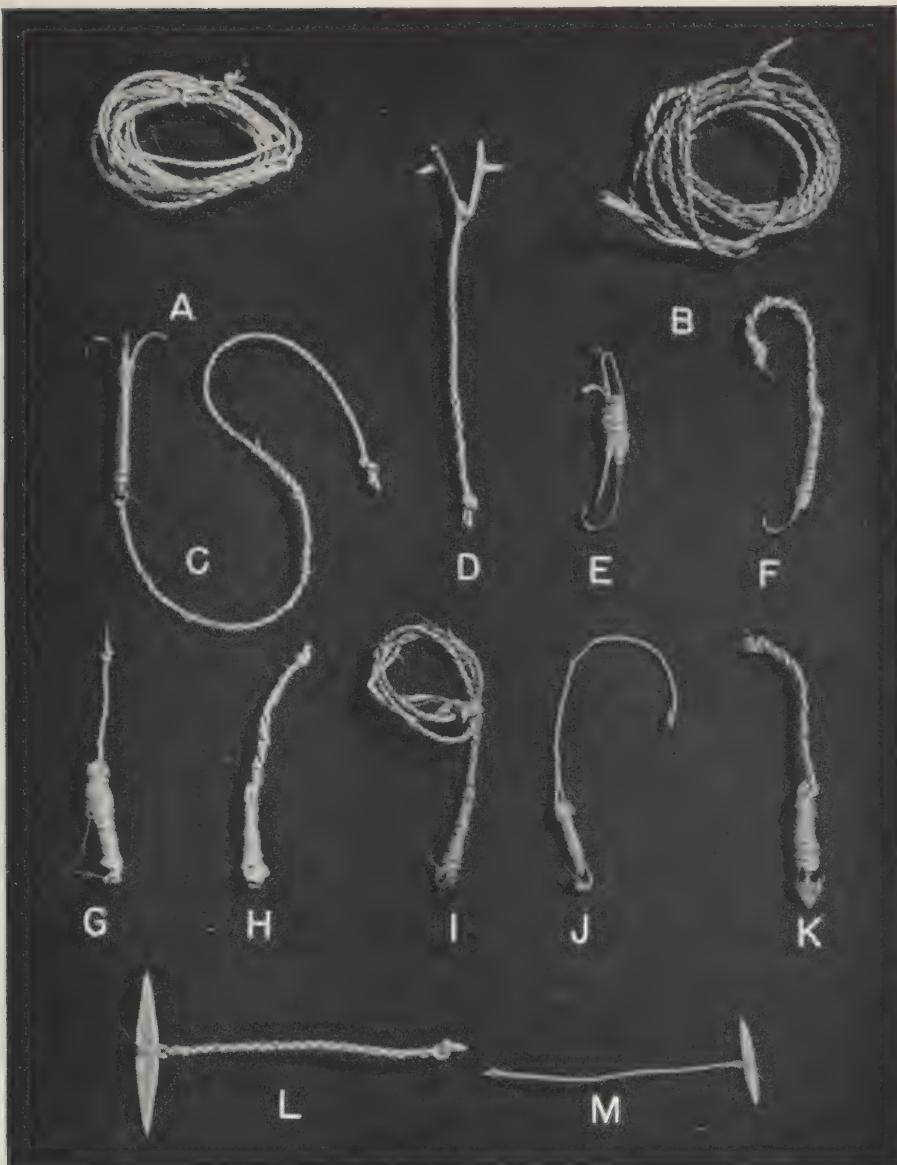

FIG. 112. Makeshift Fish Hooks. a. and b. Bark Lines; c. Triple Thorn Hook; d. Gorge Hook Made from a Thorny Vine; e. Latch Barb Hook; f. Plain Thorn Hook; g. Straight Thorn Hook with Latch; h. i. j. k. Variations of Thorn Hooks Made from Rattans and Trees; l. m. Wooden Gorge Hooks

your bait remain still. Move it slowly from time to time. When fish are scattered or are feeding near the surface, allow the bait to drift with the current. If you see fish breaking water and feeding, work your bait down to them. In all probability they will continue to feed at that spot, unless disturbed.

In clear shallow water, approach fish upstream as they lie heading into the current. Move slowly when the water is clear. If fish are shy, try fishing for them at night.

FIG. 113. Twisting a Fishing Line from Bark

#### *How to Make Hooks and Lines*

Hooks can be made from pins, needles, wire or any piece of available metal; out of wood, coconut shell, bone, thorns, flint, sea shells, tortoise shell or a combination of these. (See Figure 112.)

Lines may be made from a great variety of plants (see pp. 104-105). Inner bark of trees is best. Plant fibres and bark may be rolled into a line by twisting the fibres together. This is done by securing the knotted ends of two strands of fibres to a solid object. Holding a strand in each hand, twist them clockwise and then cross one above the other counter-clockwise. Continue adding fibres to lengthen your cord and when necessary to keep it a uniform thickness. Two strands twisted in this manner are four times as strong as one strand, and a twenty or thirty foot line can easily be made in an hour with the more easily worked materials.

## METHODS OF CATCHING FISH

There are many technics of catching fish. The method chosen should be suitable to the conditions. Some are much more effective than the use of hook and line.

### **Set Lines**

If you have extra hooks and lines, bait and set them overnight. A skewer or gorge hook is excellent for overnight sets, as the fish have ample time to swallow the baited hook. Fasten your lines to low-hanging branches that will bend when a fish is hooked; otherwise you may lose hook, line and fish.

### **Fishing with Hands**

Catching fish with the hands is most successful in small streams with undercut banks, or in cut-off channels or sloughs where clear shallow ponds are left by receding flood waters. Reach under the bank or rocks and move your hand slowly. When you feel a fish, work your hand gently toward his head, grasping him firmly just behind the gills.

### **Spearing Fish**

Where fish are large and numerous, spearing works well. Any straight sapling with a solid core will serve as a spear. Fashion a point and harden by lightly charring it in fire. Bamboo, though hollow, is excellent. Two points should be shaped just beyond a joint. A wooden spear must often be repointed, so if time and facilities are available, spearheads of bone, shell, or stone should be shaped, or heavy thick thorns may be utilized. A knife or bayonet tied to a long straight shaft, or a large fish hook, heated and straightened is good. Try your luck with a fish spear trap. Spearing is most efficient if the fish are the kind that lie on or near the bottom or rise to the surface for air. Many species of fish can best be speared at night with the aid of a torch. A light dazzles the fish, reflects from the scales, and shows the bottom clearly.

FIG. 114. As One Strip of Bark Runs Out  
Add Another

FIG. 115. Bamboo Spear Point

FIG. 116. Thorn Spear Point

FIG. 117. Bone Spear Point

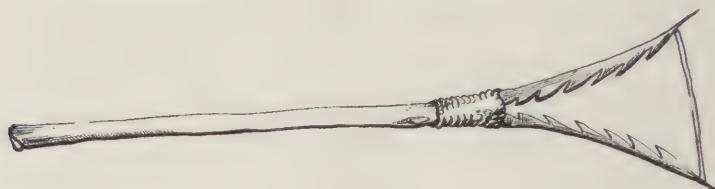

FIG. 118. Fish Spear Trap. When a Fish Is Speared the Trigger Stick Is Released and the Barbs Clamp Tight

### *Knife*

In shallow water fish can be caught by slashing them with a knife or bayonet. Clubs or machetes can be used to dispatch fish when attracted by torchlight at night in shallow water, or driven from pools over shallow riffles.

### *A Makeshift Net*

A scoop net for catching small fish or bait can be made from a piece of mosquito netting, a perforated parachute, underwear, clothing, the cloth-like material at the base of coconut leaves, or a knotted mesh of hibiscus or coconut fibres. Stitch or tie these along a circular frame made by bending together the ends of a forked sapling. If no fish are visible, hold the net on the downstream side of rocks or submerged vegetation. Muddy the water upstream and as it flows over the net, strike the rock or vegetation with a downstream stroke of your foot. At the same time scoop upstream with the net.

It is often possible to catch fish in small pools by trampling about until the water is muddy. The fish will come to the surface and can be scooped out with a net, speared, or even grabbed with the hands.

### *Poisoning Fish*

Throughout warm regions of the world there are various plants utilized by the natives for poisoning fish. The most common method of using them is to

FIG. 119. Native Crushing Derris Root (University of Kentucky)

macerate or crush the plant parts used (most often roots) and mix this in water. Drop large quantities of the crushed plants into the head of pools or small streams containing fish and within a short time the fish rise helpless to the surface. The poisonous principle is usually rotenone which is harmful to cold blooded animals, but the fish killed by it may be consumed by man without any ill effects whatsoever.

Commercial derris or rotenone can be used essentially like the crushed derris roots prepared by natives. It has no effect if dusted over the surface of a pond. It must be mixed to a chocolate malted milk consistency with a little water, then distributed in the water containing fish. If the concentration is strong, it will work within two minutes at a temperature of 70° F. or it may take an hour at 50° F. Fish sick enough to turn over on their backs will eventually die. An ounce of 12 percent rotenone will kill every fish for a half mile down a stream of the size pictured in the photograph. After putting in the poison, follow slowly down the stream and pick up the fish as they come to the surface, sink to the bottom, or swim crazily to the bank. A stick dam or obstruction will aid you in collecting fish as they float down stream. A few facts to remember about the use of rotenone are:

1. It is very swift acting in warm waters at 70° F. and above.
2. It works more slowly in cold water, and is not practical in water below 50° or 55° F.
3. It can best be applied in small ponds, streams or tidal pools.
4. Don't use too much or it will be wasted; however, too little will not stupefy the fish enough to catch.

A small container of 12 percent rotenone (1 to 2 oz.) would be a valuable addition to any emergency kit. It should not be exposed unnecessarily to air or light. It will retain its toxicity best if kept in a dark-colored vial.

Lime thrown in a small pond or tidal pool will kill all fish in the pool. Burn coral and sea shells to obtain lime.

Poisoning of fish should only be resorted to in times of emergency. A list of fish poisoning plants will prove helpful to those who must secure their own food in remote places of the world. If you have an opportunity, try to get a native of the country to point out these plants and if possible demonstrate their use.

### **Some Fish Poisoning Plants**

*Anamirta cocculus* (tuba) is a climbing plant found in the South Pacific Islands and southern Asia. The crushed seeds thrown into water will stupefy fish.

FIG. 120. Gathering Fish Poisoned with Derris

FIG. 121. Pick up the Fish as They Come to the Surface

Plants of the genus *Derris* (tuba) are climbing shrubs or woody vines used throughout the tropics to kill fish. The powdered or macerated roots are mixed in water and thrown into pools or streams.

*Duboisia myoporoidea* is an Australian shrub with white axillary clusters of flowers and a berry-like fruit. The crushed plants are thrown into water to kill fish.

*Croton tiglium* (tuba-tuba) is a small shrub or tree with seeds borne in three-angled capsules. It is found in waste places of the islands of the South Pacific region and does not occur in the forests. The pulverized seeds of the fruit will kill fish.

*Tephrosia* (tuba) contains numerous species of bean-like shrubs widely used in the tropics to poison fish. The leaves and stems are crushed and bruised and whole bundles thrown into the water.

FIG. 122. *Anamirta cocculus*

FIG. 123. *Derris elliptica*

*Barringtonia asiatica* (tuba-tuba) and related species are large trees, usually found near the sea, in Malaya and parts of Polynesia. The fruits are fleshy, more or less four-angled in cross section, and one-seeded. The crushed seeds are mixed with bait or thrown into a pond.

*Lonchocarpus* (barbasco, cube, timbo, haiari) is a group of plants, small trees, or woody climbing shrubs with alternate pinnate leaves found in tropical America and the West Indies. The flowers vary in color but are never yellow. The powdered or macerated roots are used for fish poison.

FIG. 124. *Duboisia*FIG. 125. *Croton tiglium*FIG. 126. *Tephrosia*FIG. 127. *Barringtonia*

The stems, seeds, pods, and roots of various species of *Mundulea* in tropical Africa are utilized according to the species.

### **Swimming to Catch Fish**

Fish seek concealment and shade, so if the water is clear and there are large rocks on the bottom, swim down and feel under them just as you might do in catching fish under a bank. Slip into the water quietly and swim slowly beneath the surface until you can get close enough to strike a large fish with a hook or gaff attached to a wooden handle and line. Drop the gaff after striking the fish and haul your prize in upon regaining the bank.

### **Shooting Fish**

Fish can be shot with a sidearm or gun. Aim well under them. A hand grenade thrown into a stream or school of fish will furnish all you can eat.

### **Ice Fishing**

When ice is clear enough for fish to be seen, you can stun them by striking the ice above them with a large rock or the butt end of a log. Chop a hole and

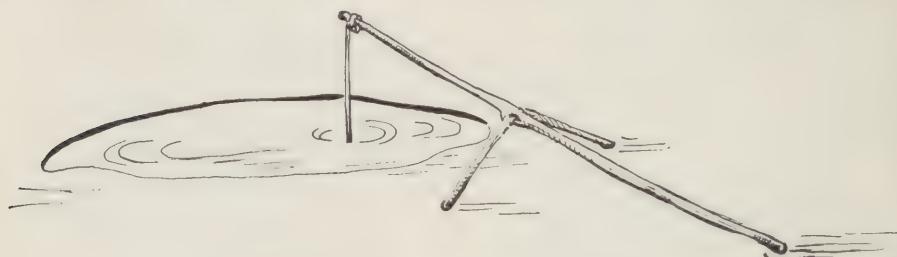

FIG. 128. Ice Fishing

pick up the fish. This method is most effective in shallow water. When water is deep and the ice thick, cut a hole and fish through it. If possible, build a brush shelter and fire nearby. Rig up an automatic signalling device so you can watch several lines at once.

### **EELS**

Eels are fish with a snake-like appearance, found throughout the world in both fresh and salt water. They are smooth skinned and swim under water. Snakes are scaled and usually swim on top. Eels are excellent eating and can be caught in muddy water or at night by using many of the methods described for fish. They are easily speared at night under a torchlight. After catching them, strike them a sharp blow toward the end of the tail to stun them. Eels, like catfish, should be skinned before cooking.

## FROGS

Skin frogs before cooking them, as many species secrete irritating and poisonous fluids from their skins. Particularly avoid those marked with yellow and red. Frog legs are a real delicacy, but there is no reason why you shouldn't eat the entire body. Frogs are widely distributed throughout the world in warm and temperate climates and are found along the banks of streams, lakes, ponds, swamps and marshes.

FIG. 129. Frog

FIG. 130. Salamander

At night frogs may be located with a light or by their croaking. Approach slowly. In warm weather when frogs are active, club them with a stick. Snag the larger ones with a hook and line. Frogs are very tenacious of life and frequently escape after they are stunned. Stick your knife through the spinal cord just behind the head.

## OTHER AMPHIBIANS

Newts, salamanders and other amphibians are found in some of the places where you find frogs. They can be seen swimming in the water or crawling on the forest floor at night. In the day they can be caught by looking under rocks, in streams, damp woods and under rotting logs. All of them are harmless. They inhabit fresh water only. The best way to catch them is with a dip net.

Skin and gut them, but avoid eating parts that contain glands.

## MOLLUSKS

Mollusks such as terrestrial and aquatic snails, and bivalves similar to our fresh water mussel are found the world over under all water conditions. All of them are edible, but they should never be eaten raw. They may carry parasites causing serious diseases, or be contaminated from polluted water. You can usually pick them up in your hands or locate them by feeling around in the mud with your feet. Streams and rivers are the best places to look for them.

FIG. 131. Look for Fresh Water Mussels Along All Streams

Seek out the shallow water with a sand or mud bottom in which mussels can bury themselves, and look for the narrow trails they leave in mud, or for the dark elliptical slit of their open valves.

#### CRUSTACEANS

Crabs, crayfish, lobsters, shrimps, and prawns are found in fresh water throughout the world. All of them are probably edible, but they spoil rapidly

FIG. 132. Fresh Water Shrimp

and some contain parasites harmful to man. They should always be cooked. The salt water forms can be eaten raw with little danger provided they are fresh.

Fresh water crabs and crayfish can be scooped up in a dip net or picked up from moss beds under rocks and brush in streams. Many species of crabs and lobsters are nocturnal and can be most easily caught at night. This is particularly true of the land crabs. All the meat within the skeleton of crabs, crayfish, and lobsters can be eaten, but the gills are usually discarded, since they are the first to spoil.

Fresh water shrimps are abundant in tropical streams. They can be seen swimming or found clinging to branches or vegetation in the water. Look for them along a stream where the water is shallow and sluggish. The shelled tail is the part most commonly eaten.

Prawns will rise to a light at night and can be scooped off the surface of the water.

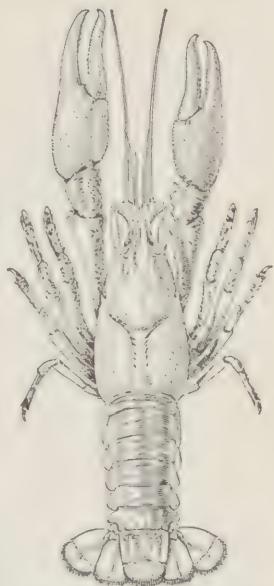

FIG. 133. Crayfish

## REPTILES

### *Lizards, Snakes, Turtles, Alligators*

Fresh water snakes frequent sluggish water, rocky, muddy and vegetation covered banks, piles of driftwood and overhanging bushes. In such places they bask in the sun when it is not too hot. All of them are edible, some

FIG. 134. All Lizards Are Good to Eat

delicious, but caution should be used in securing them, as the bites of some are fatal. Land snakes, including the poisonous species, are also edible. (See page 200.)

Lizards are found almost everywhere. They are most abundant in the tropics and subtropics. They can be clubbed, and they are easily snared with a grass or bark noose on the end of a stick. Remove their scaly skins and broil or fry the meat. There are only two poisonous lizards and they are confined to the American Southwest, Mexico and Central America; their flesh however can be eaten. Many of the lizards such as the monitors, inhabiting southern Asia, Africa, and Australia, look exceptionally fierce and dangerous. In spite of their appearance, however, they are good to eat. The flesh of iguanas is much like white meat of chicken. Crocodiles and alligators are also good to eat. Skin them by first heating over a fire to loosen the plates.

Turtles are found over most of the land areas of the temperate and tropical zones and in nearly all the waters of the earth. The marine, fresh water, and land forms are all edible. Small fresh water ones can be grabbed or clubbed on the bank or caught on hook and line. Most of them are slow swimmers. In clear water, you can catch a turtle by swimming under water. Grip well to the rear of the shell, but don't try this technic on the large forms such as the snappers. They can inflict a serious bite.

FIG. 135. Look for Grubs in Rotten Logs

### INSECTS

Insects are abundant throughout the world and the larvae or grubs of many are edible and nourishing. Insect forms of one kind or another live in prac-

tically every conceivable habitat. Grubs are found in rotten logs, in the ground, and under the bark of dead trees. They should be boiled or fried, but they can be eaten raw. Grasshoppers should always be cooked, as some contain harmful parasites. Termites are a native delicacy, cooked or raw, and in jungle country they are generally available. Be cautious of eating caterpillars, as many are irritating and some are poisonous.

FIG. 136. Immature Termite

FIG. 137 White Grub

### BIRDS AND MAMMALS

Birds and mammals are edible and easily seen, but they are usually the least abundant or available forms of animal life in an area.

First seek the lower animals such as fish, reptiles, insects, crustaceans, and mollusks for food. They are far more abundant and much easier to obtain.

FIG. 138. Keep Your Eyes Open for Nests Containing Eggs

When you have satisfied starvation pangs by eating them, you may consider ways and means of catching the birds and mammals. This is only a very general rule and of course there are many exceptions. In the far north mice and rabbits are often the most numerous and available source of food, and

at nesting colonies birds may be caught by the hundreds. As all birds and mammals are edible, it is not necessary to recognize specific ones, but it is necessary to know their general, and, where possible, their specific habits in order to obtain them for food. You must be able to secure them for any prolonged stay in wilderness areas.

### ***General Principles***

A few general principles concerning birds and mammals will prove helpful in hunting or trapping them:

1. Land animals make conspicuous signs, such as, tracks, feces, runways, trails, dens, and feeding marks that serve as indicators of their presence and relative abundance. Look for such signs. They will tell you whether it is worth while to stop or to continue to a more favorable place.

2. Many mammals large and small travel on trails and runways. This is especially true of small rodents such as mice, ground squirrels, rabbits and ground hogs. By hunting and trapping along these trails you eliminate large areas of less suitable ground.

3. Birds and mammals are creatures of habit. Their normal daily activities of eating, sleeping, drinking, and traveling are fairly regular, and continuously repeated. If you observe them, you can anticipate their movements. They can be hunted or trapped most successfully during their periods of activity.

4. Birds are less fearful of man during the nesting period than at any other time, and with patience you can catch them. Their nests and young are generally well hidden, but they can be located by watching the parent birds which return often and regularly. Birds nest in every conceivable habitat—rocky cliffs, sandy beaches, marshes, on trees, in the woods and in the fields. Some live in colonies. In the tropics, some birds are nesting all year round. Spring and early summer are the seasons to look for bird eggs in temperate or arctic regions.

5. Birds and mammals tend to congregate in the most favorable habitats. Some of the places to look for them are:

- (1) The edges of woods and jungles.
- (2) Trails, glades, and openings in forest or jungle.
- (3) Streams and river banks.
- (4) Lake and ocean shores.

A. In some environments such as tropical rain forests and desert regions, more mammals are active at night than during the day. Thus a country seemingly destitute of life during the daytime may "become alive" at night.

- (1) Hoofed animals forage both day and night.
- (2) Many rodents and carnivores are active only at night.

B. Birds and mammals are most active early in the morning and late in the evening and are generally quiet during the middle of the day.

6. Birds detect danger by sight and hearing but rely little, if any, on a sense of smell. Most mammals, in addition to good eyes and ears, have a keen sense of smell.

8. Animals have natural camouflage, but movement makes them visible. Stop often when hunting for food. By doing so you become less visible and the animal life that has "frozen" at your approach begins to move. You may see more animal life in one hour of sitting than in several hours of hiking.

FIG. 139. Fixed Rabbit Snare Across Trail. (Fish and Wildlife Service)

A few examples will be helpful in illustrating how some of these principles can be applied specifically to food getting. When you enter an area of open country where mice, voles, and lemmings are abundant, you will see trails and ground tunnels crisscrossing through the grass and weeds. If the vegetation is matted or snow covers it, you may have to kick under it to observe these signs. In addition, there will be tiny droppings in the trails and in some cases the bases of bushes and trees will be white where the bark has been gnawed completely off. Here is a place to stop and get food. Upon closer observation you will probably see mice scurrying ahead as you walk. Lift up logs and kick into all matted or dead grass. You can club these small mammals or step on them. They don't move about more than a few hundred feet. In the woods, knock open hollow logs and standing hollow dead stubs and investigate all round grass or leaf nests in trees or on the ground.

Wherever rabbits or hare are fairly abundant, you will jump seven or eight in an hour's walk. You will find them "bedded down" in grass on a

sunny hillside, in brambles, or among vegetation at the base of trees or logs. If you see one bedded down, approach slowly and shoot or club it. Before retiring for the night, set snares in runways. If snow is on the ground, these runways will be clearly evident by the tracks. In the north, rabbits and hare seek out the swamps during the winter and are concentrated in these habitats. If you jump a rabbit, don't shoot at him on the run. Whistle shrilly and the chances are that he will stop just before disappearing into the brush. That's your chance for a still shot. These are only a few of the countless ways in which you can utilize animal habits in your search for food.

FIG. 140. Set Snares in Runways

### TRAPPING

Any trap to be effective must be constructed and set with a knowledge of animal habits. There is no "catch all" among traps. A trap set at random to catch whatever chances to come along is worthless. Decide upon the kind of animal you wish to trap, bait your snares with the kind of food it eats, and keep the surroundings as natural as possible.

*The fundamental principle of successful trapping is to determine what the animal you wish to trap is going to do and then catch him doing it. It is easier to determine this for some animals than others.*

Small mammals such as mice, rats, rabbits, or squirrels are most easily

trapped, because their activities are confined and regular and thus more easily anticipated.

Remember that wherever birds and mammals are naturally abundant, or for one reason or another are congregated or follow very definite and observable habits, trapping will prove effective.

FIG. 141. Rabbit in a Hanging Snare

### Hanging Snares

A snare is a noose that will slip and strangle or hold any animal caught in it. It is fastened to the end of a bent pole or sapling, and spread open in a well worn runway or in front of an animal den or bird nest. The size of the loop will vary with the kind of animal to be trapped. Make it large enough to admit the animal's head, but not its entire body. *On a rabbit trail the loop should be about 4" in diameter and hang 1 1/2" to 3" above the ground.* The trigger or cross piece holds the sapling down until an animal puts its head in the noose and with a jerk frees the trigger. The bent sapling lifts the animal off the ground where it soon strangles.

FIG. 142. Running Bowline

### Fixed Snare

Fixed snares are fastened to stationary objects such as logs, trees or a forked stake. (See Figure 139.) To be most effective the snare should be set near a bush or limb where the animal will get tangled and strangle itself while struggling. This is particularly useful for catching rabbits and hare.

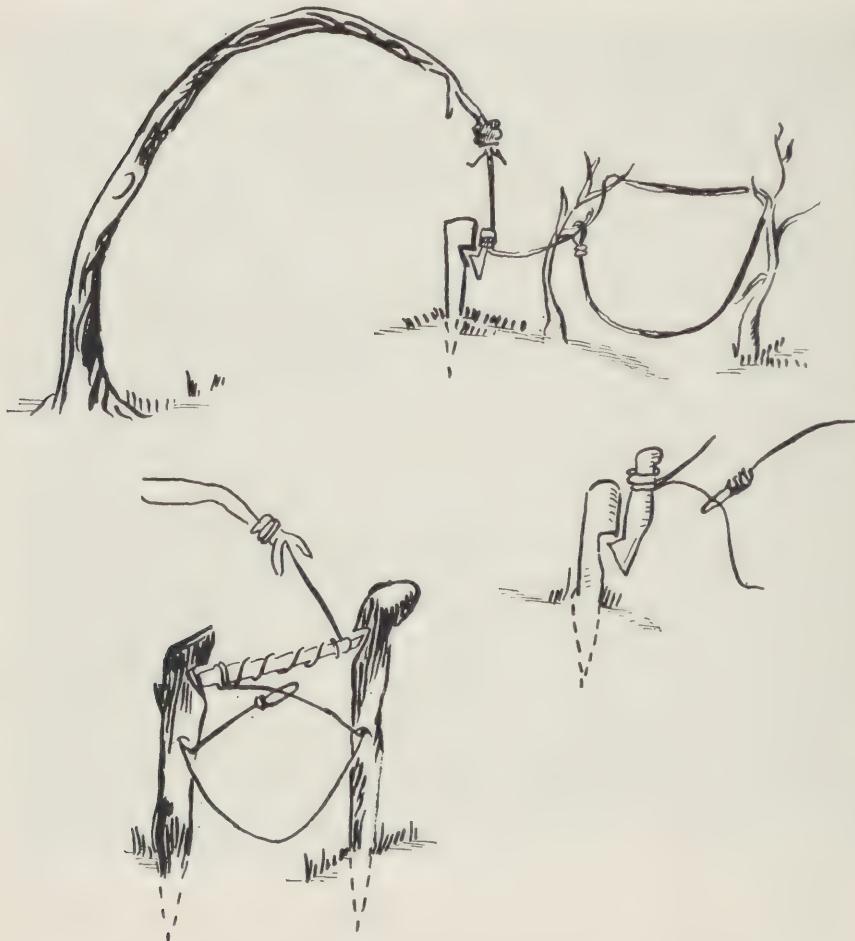

FIG. 143. Hanging Snares Set on Trail. Closeup of Triggers

In the jungle, small mammals and especially birds such as pheasants and jungle fowl are more readily snared by building a low fence of sticks on either side of the runway to lead them to the trap. The treadle spring snare is very effective for such a set. A spear trap should be used for large mammals. (See Figures 145 and 146.)

### Deadfalls

Deadfalls will trap both birds and mammals and the basic principles can

be infinitely varied to meet specific conditions. The trigger should be long and the weight tilted at a steep angle. Place a small flat stone under the upright so that it will not sink into the ground. Bait the trigger and the trap will fall when the bait is disturbed. The bait should always be tied on before the trap is set. (See Figure 147.)

These traps can also be sprung with a long string or strip of bark. If they are placed in front of a den or over a regularly used trail, no bait is necessary.

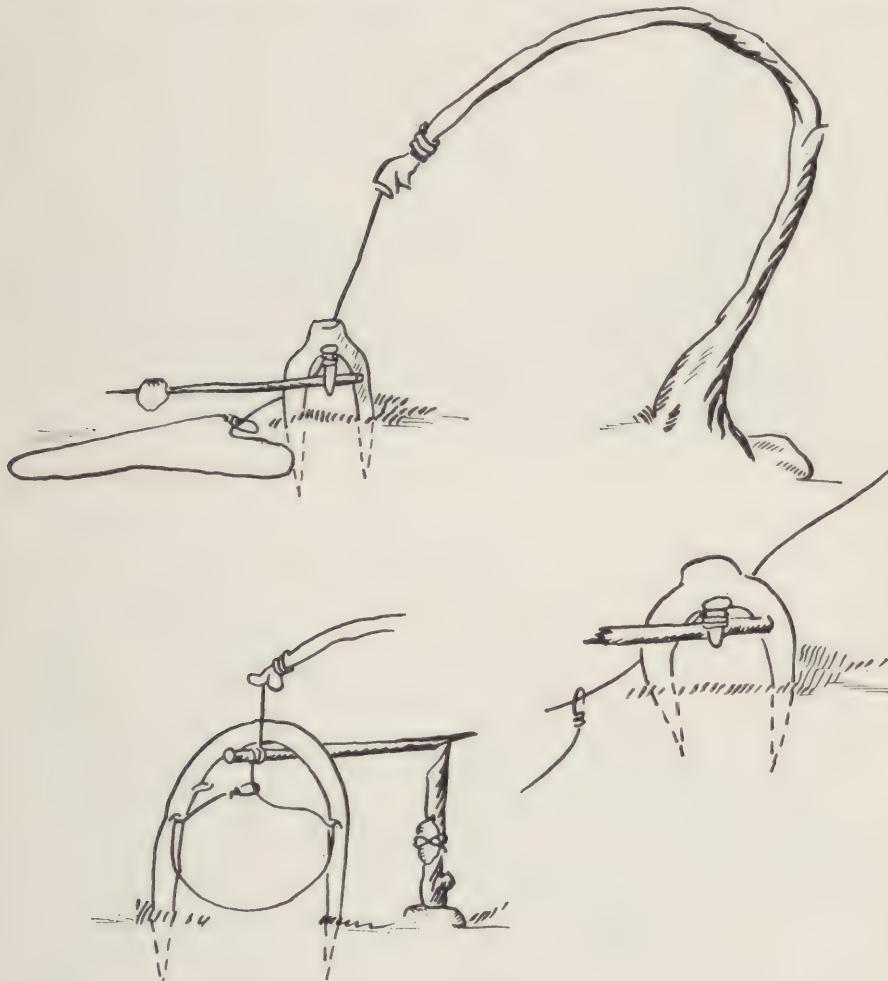

FIG. 144. Baited Hanging Snares and Triggers

#### *Trapping with Bird Lime*

Bird lime is any strong adhesive (generally made from the sap of plants), used to catch birds just as flies are caught with fly paper. This method of

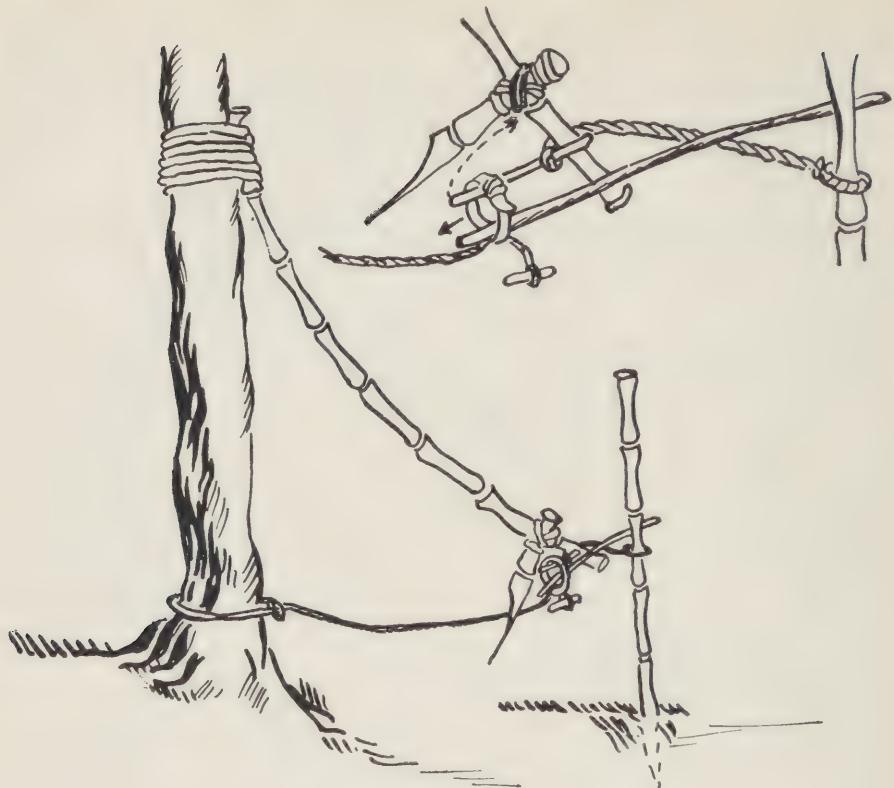

FIG. 145. Spring and Spear Trap

FIG. 146. Treadle Spring Snare. Treadle Should Be Covered with Leaves or Grass

FIG. 147. Deadfall with Figure Four Trigger

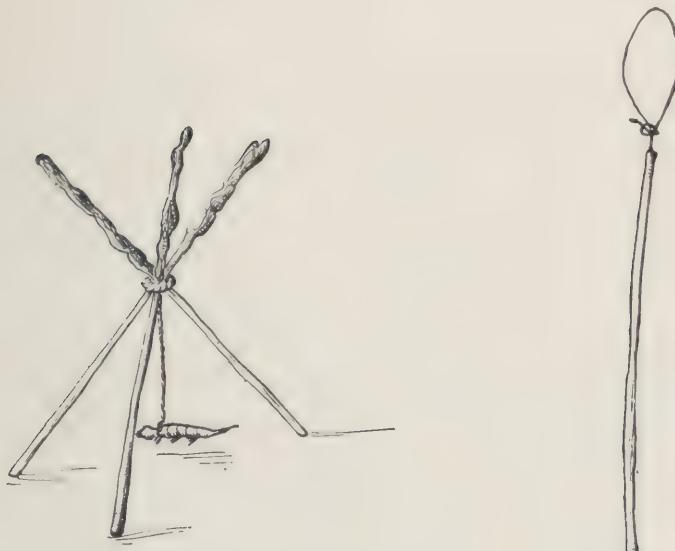

FIG. 148. Tripod Smeared with Bird Lime  
and Baited with a Mole Cricket

FIG. 149. Noosing Wand

trapping is common in many parts of the world. The adhesive is usually smeared on slender sticks that adhere to the wing of birds and prevent flight.

When using bird lime, study the habits of the bird you wish to trap so you can set the sticks where they will come in contact with its wings. A tripod of sticks baited with an insect is often effective. (See Figure 148.)

The sticky qualities of bird lime are neutralized by dust. Try to place your sets in dust-free areas, but if this is not possible, lose no time in grabbing the entangled bird.

Bird lime can be used in either jungle or desert, but it is not effective in cold weather. It can be made by boiling the sap of various Euphorbias. In many places bird lime is made by boiling sap of fig trees. The sap of the bread-fruit tree swells when exposed to air and forms a glutinous substance utilized as bird lime. In parts of South America it is made from the milky sap of the Sapodilla tree which furnishes chicle for chewing gum. Heated chewing gum makes a good substitute and is supplied in emergency rations.

### *Trapping Tricks*

Squirrels, coons, opossums, and other mammals that live in hollow trees can be extracted by inserting and twisting a short forked stick. Pin the animal against the side or bottom of the hollow and then twist the stick. The fur and loose skin will twist around the fork and the animal can be pulled out. Keep tension on the stick when withdrawing. A short fork takes a secure hold, a long fork does not. These same mammals can be smoked or drowned out of dens and clubbed as they emerge.

There is no better way to attract mammals to a trap or within shooting distance of a hide than by placing salt along a trail or at a water hole.

A noose fastened to the end of a long pole can be used to snare an animal as it comes out of its burrow. If there is more than one entrance to the burrow, block all but one. Roosting and nesting birds can also be noosed in this manner. Some birds can actually be touched while incubating eggs or brooding young; others are more wary. All will return to their nests or roosts provided the surroundings have not been too greatly disturbed. Conceal yourself by building a blind of vegetation and remain still and quiet within. Drop the noose over the head and pull up and back against the bill.

Birds that nest in hollow trees such as woodpeckers, owls, hornbills, etc., can be blocked in the hollow tree or noosed as they go in or out.

A tethered live bird acts as a decoy for other birds of the same species. Imitation distress sounds and calls will lure some birds within striking or noosing distance. A very effective distress sound can be made by kissing the back of your hand.

A fish-baited hook placed along the beach or in the water will catch shore

birds, herons, and fish-eating ducks. Gulls, terns, albatross and other ocean birds can sometimes be caught by trolling slowly with a minnow or piece of fish.

When all else fails, resort to fire. Game, nesting birds, and lower animal forms can be burned or driven out by setting fire to open grasslands. This cruel and wasteful method is not to be considered unless your life hangs in the balance.

If you learn a few trapping technics, if you are resourceful, and, above all, if you observe the habits of the wildlife, you should be able to obtain enough wild meat to sustain you. In the wilderness, resourcefulness and observation are your greatest tools.

### HUNTING PRINCIPLES

Game animals rely upon their senses of sight, hearing and smell to detect danger. Some have only one or two of these senses highly developed, while others have all three. An experienced hunter takes advantage of the shortcomings of his quarry; the novice, however, when hunting unfamiliar game should proceed on the assumption that they are naturally wary and that they possess keen senses of sight, sound and smell. Be over-cautious until experience indicates the best hunting technics for the quarry at hand.

To be consistently successful in hunting, you must know how to *find* game, how to *approach* game and how to *shoot* it. In a tough spot you may have only one chance; a failure may mean your life. Learn a few do's and don'ts of hunting.

*Some of the hunting principles that follow can be applied to almost any type of mammal shooting, but are especially applicable to large game such as deer, antelopes, caribou, sheep, goats, buffaloes, and wild boar.*

#### **Finding Game**

1. The greatest advantage you can have in hunting is to see your quarry before it sees you.
2. Look for fresh signs such as tracks, beds and warm or moist droppings; they indicate the recent presence of game.
3. Whether in the woods or in the open, peep cautiously over ridges, examining first the distant and then the closer ground.
4. *In the woods move slowly and stop often. A motionless man has an immense advantage over a moving animal.*
5. One of the surest ways to get a shot is to locate a water hole, feeding ground, or well traveled trail and wait quietly for the game to come to you.
6. In dense forested country where the range of vision is limited and the

FIG. 150. Elk—Stalk Game by Utilizing Their Habits and You'll Get a Shot

FIG. 151. Mountain Sheep—With Patience You Can Get Close Enough for a Shot

game must be closely approached to be seen, *silence* is essential. Avoid treading on dry sticks and leaves or brushing against bushes.

7. In open or mountainous country game is generally seen and shot at a distance. Silence is not such an important factor as in the woods, but you must keep under cover.
8. Whether looking for game or stalking it, move up or across wind, never down wind. This applies equally in open or forested country. Go out of your way to utilize cover and contours even if it requires a wide circuit.
9. In open country keep the sun behind you, as it is difficult to shoot into the sun. You will be less visible to the game and it will be more visible to you.
10. If your quarry has sighted you but has not fled, do not approach it directly; tack back and forth across your line of approach. Move when the animal is feeding and freeze when it looks up or ceases the activity that is absorbing its attention.
11. Get above mountain game; it seldom suspects danger from above.
12. Never silhouette yourself on a skyline, as you become immediately visible and suspicious to game.
13. Camouflage your clothing so it blends with the landscape.

### *Shooting Game*

14. Never make a shot unless it is the very best you can do. Take your time, for a miss will scare the game and increase your difficulties many fold.
15. Many animals are curious of strange noises and objects and can be made to stand for a good shot, or to approach within range by attracting their attention with a whistle or moving cloth.
16. The head, neck, or just back of the shoulder are vulnerable spots on many animals. Aim for one of these.
17. Don't follow a wounded animal too closely; give it time to bleed and weaken, otherwise it may run for miles.

The principles of hunting set down here will prove invaluable to the novice, but remember that a knowledge of the habits of the game and the locality are equally important factors in successful hunting. Your chances of success increase with each day spent in hunting an area or a particular animal, so don't be discouraged if at first you are unsuccessful.

TABLE 1

SOME PLANTS FROM WHICH CORD, LINES AND  
ROPES MAY BE MADE

Throughout the world there are numerous plants whose roots, outer and inner barks, and leaf and stem fibers can be twisted and used as cord or rope for fishing, lashing and climbing. Fiber from palms, rattans, bamboo and various vines are common in the tropics. The tough inner or outer bark of trees is the easiest and simplest material to use. Soaking often helps to separate the fibers.

NAME	PART USED	WHERE FOUND
1. Leather wood ( <i>Dirca</i> )	Strands of split bark.	Eastern North America.
2. Basswood or Linden ( <i>Tilia</i> )	Shredded layers of inner sapling bark.	Temperate countries of north- ern hemisphere. Rich humus soil.
3. Mulberry ( <i>Morus</i> )	Inner bark of trunk and roots.	Temperate regions of north- ern hemisphere.
4. Spruce ( <i>Picea</i> )	Barked rootlets.	Cold climates of northern hem- isphere. Southern mountainous country.
5. Hemlock ( <i>Tsuga</i> )	Fibers of roots and the roots themselves.	Northern North America and Southern mountains.
6. Tamarack ( <i>Larix</i> )	Fibers of roots.	Cold climates of northern hem- isphere. Swampy wet region.
7. Elm ( <i>Ulmus</i> )	Shredded bark of trunk and roots.	Temperate climate of northern hemisphere.
8. Indian Hemp ( <i>Apocynum</i> )	Bark fibers.	Temperate regions of north- ern hemisphere. Open land.
9. Yucca	Fibers in leaves.	Southern United States, Mex- ico, tropical America. Many are semi-desert plants.
10. Breadfruit ( <i>Artocarpus</i> )	Strands of inner bark.	South Pacific Islands, Malaya, Southern Asia.

NAME	PART USED	WHERE FOUND
11. Plantains & Bananas ( <i>Musa</i> )	Fibrous tissues in mature leaf stalks.  <i>Musa</i> produces manila hemp.	Throughout tropical and sub-tropical countries.
12. Coconut palm ( <i>Cocos</i> )	Fibers of coconut husks and midrib of the leaves.	Throughout tropical countries.
13. Liana ( <i>Entada scandens</i> )	Whole smaller stems and fibers of large stems.	Native of tropics of both hemispheres.  South Pacific Islands. Also furnishes drinkable sap.
14. High climbing fern ( <i>Stenochlaena palustris</i> )	Wiry stems, very durable under water.	India and South Pacific Islands. Another species in Africa and Madagascar. Found in swamps or near the sea.
15. Climbing Cane ( <i>Flagellaria</i> )	Stems.	India, Australia and South Pacific Islands.
16. Climbing or scrambling aerial plants. ( <i>Freycinetia storkii</i> )	Flexible stems.	Indian Archipelago, New Zealand, Pacific Islands, etc.
17. A climber of open country. Stem fibers. ( <i>Pachyrhizus erosus</i> )		Tropical America, East and West Indies, South Pacific Islands. Found in thickets in open country.
18. Common tropical weeds ( <i>Urena sinuata</i> and <i>lobata</i> )	Fiber from inner bark.	Common in tropics.
19. Shaw trees ( <i>Sterculia</i> )	Fibrous inner bark. Rope not affected by wetness.	Tropics of both hemispheres.
20. Wild Hibiscus ( <i>Hibiscus cannabinus</i> )	Stem fibers.	South Pacific Islands.
21. Screw pine ( <i>Pandanus</i> )	Leaf fibers.	South Pacific Islands.

## CHAPTER VI

# Firemaking and Cooking

Fire will lengthen your survival time by enabling you to keep warm, cook your food, and destroy the harmful germs commonly found in food and water. You should be able, with matches, to build a fire under all weather conditions. No one who may have to shift for himself in a remote area should ever be without matches carried in a waterproof case. If you remember and practice a few basic principles of fire building, you can always make a fire.

- (1) Select a dry sheltered spot.
- (2) Use only the driest of tinder to start the fire.
- (3) Have a good supply of kindling on hand before you strike the match.
- (4) Start with a tiny fire and add fuel as the flame grows.
- (5) Fire needs air. Add fuel sparingly.
- (6) Blow lightly on the burning wood. This helps the flame along.
- (7) Fire climbs. Place fresh kindling above the flame.
- (8) Use dry dead wood.

FIG. 152. Fire with a Camera Lens

### **Fire Site**

Use judgment in the selection of a fire site. Don't select a windy spot. Don't build on damp ground if dry is available. Pick a spot where your fire won't spread. In rainy weather, build under a leaning tree or rock shelf. If snow is on the ground, build your fire on a platform of logs, or metal salvaged from your plane; however, you can build or keep a fire going on bare snow or ice.

### **Tinder**

Tinder may consist of dry grasses or plant stems, dry inflammable bark, such as birch, or dry leaves. The most available tinder in dry weather is the tiny,

FIG. 153. Use Small Dry Tinder

brittle branchlets from dry, dead limbs. Twigs not much thicker than a straw should be broken in lengths of several inches and arranged in a wigwam pile three to four inches high, the shortest and thinnest twigs being underneath. Touch a match to these and add kindling as the flames grow. A fuzz stick or shaving clusters may be used in place of small twigs. Select some dry branches the diameter of your finger and shave them halfway through for most of their length to form a cluster of shavings. Stand these in a wigwam with curls down, and light them.

### **Kindling**

Have plenty of kindling at hand to keep your fire burning. Soft woods make the best kindling as they light easily and burn rapidly. Split wood burns faster than round branches. Branches lying flat on the ground are generally damp. Select dead branches off the ground. Most dead branches snap when broken. Live ones bend and are usually not brittle.

### **Fuel**

All woods do not burn alike. Some scarcely burn at all, others burn quickly

and make a hot flame. Some burn slowly and make good coals; some smoke, others don't. Use whatever is at hand, but where there is a choice, select the best fuels for the purpose. In general, hardwoods make a slow-burning fire with lasting coals, and soft woods make a quick, hot fire with coals that are soon spent.

In the Arctic fire is essential. Dried lichens, moss, heather, scrub willow, and driftwood all make good fuel. The resinous white heather is the most valuable arctic prairie fuel. Willows and alders grow along practically all arctic rivers, and their stems and roots alike serve as fuel. Even in mid-winter, willows can be found in wind-swept spots.

Seal blubber is the best natural fuel. It can be burned in a shallow stone lamp or tin can with a wick of thoroughly dry powdered moss, grass or decayed wood. Another method is to soak a small piece of cloth in seal grease. Then place a small pile of dried bones or other non-combustible material on top of the rag. Lay several strips of blubber on top of the bones and light the rag, which will burn like a wick and start the blubber frying. The blubber oil will trickle down on the bones and flare up as soon as they become hot. Fat and hides of land animals are also usable fuel.

Lubricating oil will not light with a match unless first vaporized by dripping on a piece of hot rock or metal. It can, however, be burned in a container with a wick of rope, cloth, dried bark or moss. If you come down with your plane in the Arctic, drain your oil before it congeals, mix it with gasoline, pour it into a container and burn it with an improvised wick.

### ***Banking a Fire***

It is essential to bank a fire properly if you expect to have it burning the next morning or the next week. Use green logs or the butt of a decayed punky log for a slow-burning fire. Eliminate as much draft as possible. The coals or the charred backlogs can be blown into a flame when needed. Dry coconut husks, punk and fungus are excellent for keeping a fire going and for carrying it from place to place. It requires less work to keep a fire going than to start a new one.

### ***Fire in Wet Weather***

The trick of making a fire in wet weather is to find enough dry tinder and wood to get it started. Even wet wood will burn on a good fire. Look for dry wood under overhanging rocks, in caves, on the under side of leaning trees and logs, and in hollow trees. Rain does not soak far into a standing dead tree; split it open and use the interior. Cut away the wet exterior of small dead limbs to get dry wood. If your matches become wet, you can dry them by rotating them rapidly between the palms of the hands.

*In wet weather, a fire can be started with certain inflammable tinders that will ignite even when damp.* The resinous pitch in pine knots or dried stumps burns like an oil torch. Slivers of dry pitchy pine make excellent tinder and kindling. The loose bark from living birch trees contains a resinous oil which is easily ignited and burns fiercely.

### **Fire Without Matches**

*Sun and glass.*—Sunlight focused on a pile of tinder through the lens from a flashlight, binoculars, telescopic sight or camera, will produce coals that can be fanned into a flame. It may be necessary to take the lenses apart and use a single element.

*Flint and steel.*—Sparks struck from a piece of flint, quartz or pyrite into a pile of tinder can be used to start a fire. Use the back of your knife blade

FIG. 154. Fire Thong

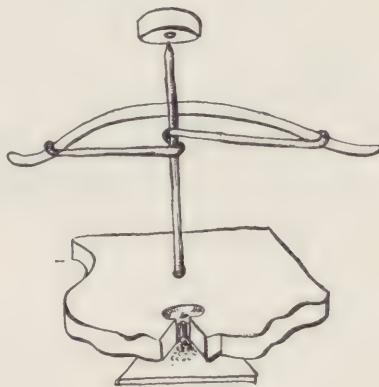

FIG. 155. Bow and Drill

or any piece of hard steel to strike the sparks. Let the sparks fall on a spark-catcher of shredded cloth, dry moss, bird and seed down, dead fungi, punk or pulverized bark. Once the spark catches, blow it gently until it flames. Experiment with the driest tinders you can find. Charred rags catch better than anything else; so if your matches are running short, char some of your clothing by burning it without air in a closed container such as a tin first-aid kit or a ball of clay.

*Wood friction.*—Choose dry, well-seasoned wood to make a fire by friction. Dead branches slightly punky are the best, and in general, soft-grained woods are better than hardwoods. Resinous, gummy woods are worthless. The best woods include balsa, yucca, elm and the root of willow and cotton-wood. The right kind of wood makes a fine carbon dust with the formation of an ember. If you get a coarse, gritty powder, discard the wood and try another.

*Fire with bow and drill.*—The bow and drill is the easiest method of making fire by friction. When a dry, soft shaft of wood is spun into a block of the same material, a black powdered dust will form and eventually catch a spark. Figure 155 shows the necessary materials. To make a fire with these materials, draw the bow back and forth causing the drill to spin in the block. Start slowly with long full strokes and work faster. When a volume of smoke begins to rise through the fire pit, you have a spark sufficient to start a fire. Lift the block, add tinder and blow gently until you get a flame. Fire has been made with a bow and drill in less than seven seconds.

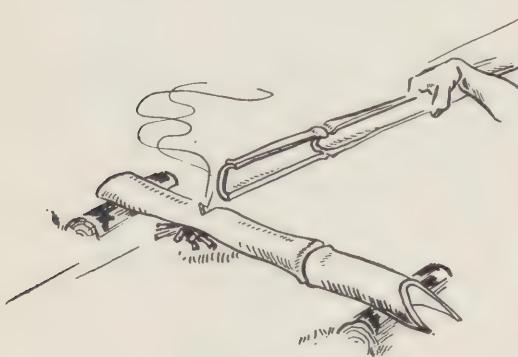

FIG. 156. Bamboo Fire Saw

FIG. 157. Keeping Warm

*Fire thong.*—Fire can be made by drawing a dry rattan thong back and forth on a soft, dry piece of wood. Wedge tinder into a split in the hearth log to catch the embers.

*Fire saw.*—The fire-saw, commonly used in the jungle, consists of two pieces of wood and plenty of "elbow grease." Split bamboo or a soft wood will serve as a rub stick, and the dry sheath of the coconut flower makes an effective base wood. Good tinder is the brown, fluffy covering on the trunk of the Apiang palm, the dry, fabric-like material found at the base of coconut leaves, and the fine, skin-like membrane lining the bamboo cavity.

These methods, however, are always a last resort, and should be tried only as such. Fire with matches is infinitely easier; always carry them in a waterproof case.

#### *Fires for Warmth*

*A small fire is better than a large one for nearly all purposes.* A very small fire will warm you thoroughly if you sit or kneel over it, draping your coat, blanket or parachute so as to direct all of the heat upward.

A reflector fire will keep you warm while you are sleeping. The base of a tree, a large rock or a log are ready-made reflectors. Lie or sit between the

fire and reflector, as this will prevent you from "baking" on one side and "freezing" on the other. A reflector can be constructed of logs, snow, boughs or sod.

### Cooking Fires

When fuel is scarce, make a hobo stove from an empty tin. Such a stove will conserve heat and fuel and is particularly serviceable in the Arctic.

The criss-cross fire is the best all-around cooking fire, as it burns down to a uniform bed of coals in a short time. (See Fuels.) The simplest fireplace consists of two rocks, two logs, or a narrow trench on which a vessel can

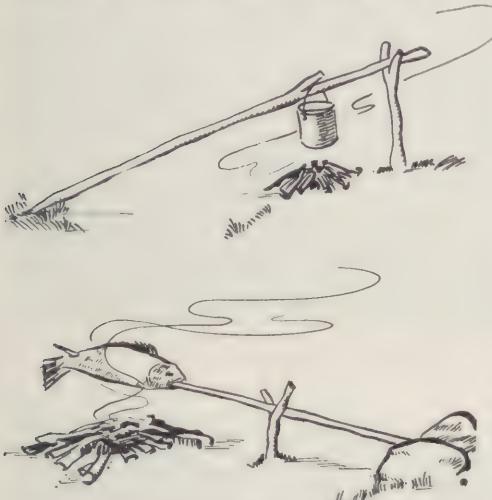

FIG. 158. Broiling Fish—Simple Crane

FIG. 159. Reflector Fire

rest with the fire below. Arrange the fireplace so that it will have a draft. If the fire does not draw well, elevate one edge of the log or stone. Replenish a fire by stacking the wood on criss-cross. It will burn to coals much sooner.

## COOKING METHODS AND TECHNICS

Cooking renders most foods more palatable and digestible, destroys bacteria, toxins, and harmful plant and animal products; cook your food whenever possible. *The best cooking is done over a bed of glowing coals, not flames.* Where containers are used, construct a crane over the fire to support the cooking vessels.

*Boiling* requires a container. When meat is tough or food requires long cooking, it is often a wise procedure to boil it first and then roast, fry or bake it. Boiling is the easiest method for the Arctic. It should be used in any case where you want to save the juices. At high altitudes, food has to be boiled longer than at low altitudes. Do not try to boil food above 12,000 feet; it requires too much time and fuel.

Water in a scooped-out log or clay pit can be boiled by dropping heated stones into it. In the tropics, half a green coconut or a bamboo stem cut well above and just below the joint can be used for containers. They will not burn completely until well after the water boils. After placing food and water in a freshly-cut bamboo joint, tie green leaves over the open end and support the vessel against a stone. (See Figures 162 and 163.)

FIG. 160. Stone, Tin Can and Log Fireplace

FIG. 161. Crane

You can boil water in vessels made of bark or leaves. The container will not burn below the water line, but it may catch fire above unless moistened. If you use a small fire and keep the flames low, you will experience little difficulty.

Birchbark and banana leaves make excellent containers. Cut out about a

FIG. 162. Cook, or Boil Drinking Water in a Bamboo Joint

FIG. 163. Cover Container and Stand Upright in Fire

twelve inch square of bark, make two diagonal folds between all four corners, open them up, turn the bark over, and fold it in thirds. Open again and fold in thirds the other way. Then pinch up each corner so that the triangle is pointing out. Fold this along the side and pin in place with a thorn, or sliver of wood. Make sure your bark contains no holes.

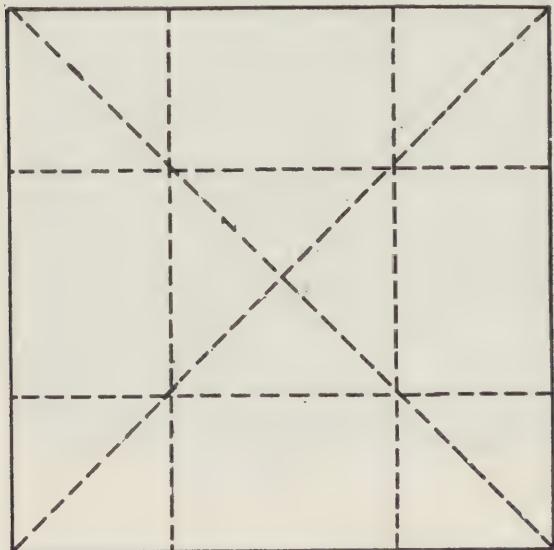

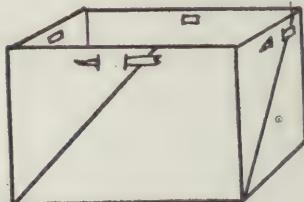

FIG. 164. Diagram for Making a Bark Container

*Roasting or broiling* is a quick way to prepare wild plant foods and tender meats. Simply run a stick through the piece to be cooked and hold it over the coals. Keep the piece as close to the coals as possible. This hardens the outside quickly and holds the juices in.

*Baking* is cooking with

moderate, steady heat in an oven. The oven may be a pit, closed vessel or a wrapping of clay or leaves. Without cooking equipment, most of your fish and meat must be either broiled or baked. To bake in a pit, get a good bed of coals,

FIG. 165. Steam or Baking Pit

then drop in a covered shell vessel containing water and meat, tubers wrapped in leaves, or fish or bird wrapped in wet leaves and mud. Cover whatever you are baking with coals, and then fill the pit with a few inches of earth. A stone-lined pit will hold more heat and cook more quickly than an earthen pit.

*Steaming* is slower than boiling, but it can be done without a container. Dig a hole and fill it with stones. Build a fire

to heat the stones. Cover the stones and coals with leaves, then put in your food. Cover this with more leaves and then a layer of dirt. Punch a hole down to the food and pour in some water. Close the hole and the food will steam. This method is suitable for foods such as shellfish that require little cooking.

## Utensils

Large leaves, a slab of bark, turtle, coconut, or sea shells will serve as plates. Some kind of container is necessary for carrying water. An excellent one can be made by punching out all but the last node from a convenient length of bamboo. Fit with a wooden plug for a stopper and sling it over your shoulder on a piece of vine. A water belt can be made of short bamboo nodes strung together.

## Cooking Wild Food

*Fruits*.—Succulent fruits are best boiled. Large, tough or heavy-skinned fruits are best baked or roasted.

*Potherbs* (Leaves, stems and buds).—Boil until tender; several changes of water with subsequent rinsing will help eliminate bitter juices or undesirable tastes.

*Roots and tubers*.—These can be boiled, but are more easily baked or roasted.

*Nuts*.—Most nuts can be eaten raw, but some such as acorns are better cooked. Acorns should be broken up, boiled with ashes from the fire to eliminate tannin, moulded into cakes and then baked. Chestnuts are good roasted, steamed, or baked.

*Grains and seeds*.—Parch grains and seeds. They are more digestible and tasty that way.

*Sap*.—The sap of plants containing sugar can be dehydrated to a syrup or sugar by boiling to remove the water.

*Large game*.—Hang the animal head down and slit the throat. Remove the entrails and the glands in the anal and reproductive regions, as they will impart an objectionable taste to the meat. Animals the size of a domestic cat or larger should be boiled first, then roasted or broiled. If meat is very tough, stew it with vegetables. Broil meat as quickly as possible over hot coals. Slow roasting makes tough meat tougher. Cook small pieces at a time.

*Small game*.—Small mammals and birds may be cooked whole or in part. If tough, or if the flavor is strong, boil first and then broil. If fruit is available, stuff the animal and bake or roast.

*Fish*.—Fish can be roasted on a grill of green sticks or baked in leaves and clay. Fish wrapped in leaves should be placed on green logs on the fire to keep the flesh free of ashes.

*Reptiles and amphibians*.—Frogs, small snakes, and salamanders can be roasted on a stick. Large snakes and eels are better if boiled first then roasted. Turtles should be boiled until the shell comes off. Then cut up the meat and cook with tubers and greens to form a soup.

FIG. 166. Cooking Breadfruit ("Yank")

*Crustaceans*.—Crabs, crayfish, shrimps, prawns, and the like can be steamed, boiled, roasted or baked. They require very little cooking. However, they spoil quickly and the safest way to cook them is to drop them alive in boiling water.

*Mollusks*.—Shellfish should be steamed, boiled or baked in the shell. They make excellent stews in combination with greens and tubers.

*Insects*.—Insects such as large grubs, locusts, grasshoppers, ants, termites, etc., can be fried, boiled or roasted, but they are generally more palatable if disguised in a stew containing other foods.

*Eggs*.—Eggs can be hard boiled with the shell on and carried for days. They can be poached in a bark container or fried on a hot rock. Turtle eggs don't get hard with boiling. Fresh eggs are among the safest of foods, and they are edible at any stage of embryo development.

*Salt*.—Salt is necessary for proper functioning of the human body. It can be obtained by boiling sea water. The ashes of burned nipa palm boughs, hickory, and some other plants, contain salt that can be dissolved out in water. Evaporate the water and a black looking salt remains.

### ***Preparing Food Without Fire***

Fresh papaya leaves contain papain that renders meat soft and tender in a short time. It is especially useful when freshly killed meat must be eaten raw or cooked.

The citric acid in limes, lemons and other citric fruits can be used to pickle fish and other flesh. Dilute two parts lime juice with one part sea water, add raw fish, and allow the mixture to stand for half a day or more. The citric acid will "cook" the fish.

## **PRESERVATION OF FOOD**

Wild food is scarce in some local areas and abundant in others. Whenever you can get more than you need immediately, preserve it, especially if there are indications that you may have difficulty in getting more.

### ***Freezing***

In cold climates, meat will be the principal food you will get in excessive quantities. It will keep indefinitely when frozen.

### ***Drying***

Drying food not only preserves it, but decreases its weight without losing any of its calories. Dry foods can be eaten uncooked when necessary. Food can be dried by wind, air, sun, or fire with or without smoke. A combination of these can be used. The main object is to get rid of the water. In hot, dry

FIG. 167. Before—Wild Food Collected in Two Hours' Time Along a River

FIG. 168. After—Same Food Cooked and Ready to Be Eaten

climates the sun and air will be sufficient, but in humid climates fire must be used and the dehydrated product kept dry. Cut the food to be dried in small strips so that a maximum area will be exposed to the drying influence.

### ***Smoke-Drying Meat***

To smoke-dry meat, build a stick grate three to four feet above a slow-burning fire, and lay strips of lean meat one-fourth inch thick on this lattice. Do not let the fire get hot enough to cook the meat or draw out the juices. The smoke which rises naturally from the burning wood is sufficient. Continue the smoking until the meat is brittle. It will then keep for long periods, and can be chewed while traveling or cooked in a stew if time permits. Avoid using resinous or oily woods to smoke meat; they will blacken it and give it a disagreeable flavor.

### ***Fish and Birds***

To dry fish, cut them in strips or split them down the back. Leave the heads on small ones and hang them over the fire by threading a stick through their gills. Small birds may be gutted and dried whole.

### ***Fruit***

Plantains, bananas, breadfruit, apricots, cherries, grapes, potatoes, tubers, leaves, figs, dates, apples, berries, in fact most wild fruits, can be dried. Cut them into fine slices and place in the sun. A fire may be used if necessary.

## **CONCENTRATED RATIONS**

Two of the best concentrated foods are pemmican and pinole. These keep indefinitely, contain a maximum of calories for their weight, are easy to prepare, and do not require cooking when used. A man can live entirely on either one for long periods. Pemmican can be made by pouring hot suet (fat) over shredded dried meat. Keep in a waterproof container and cook or eat raw.

Pinole is prepared by parching corn grains in hot ashes, on heated rocks or in an oven. The browned kernels are then ready to eat or can be pounded to a fine meal. A small handful of this in a cup of cold water has a pleasant flavor, and will keep a man going all day. Most grass seeds can be prepared in this way, though few of them will have the same nutritional properties of corn.

## **POISONOUS ANIMAL FOODS**

Animals poisonous to eat are so few that they constitute a negligible danger.

*No birds or mammals are poisonous to eat, though the liver of polar bears may cause serious sickness.*

Some sea foods are poisonous at certain times and places. Only along tropical shores, especially in the vicinity of coral reefs, is there any real danger. The alkaloids in the flesh of poisonous fish are not destroyed by cooking. (See pages 151-153.)

Spoiled meats and fish are far more dangerous to eat than animals that are themselves poisonous. Poisoning from such food is common in the tropics and constitutes a real hazard. Sea food is especially likely to spoil and should be eaten when fresh. Fish should be gutted at once to prevent spoiling. Good fish will be firm, spoiled fish soft and flabby.

Meat and the flesh of all fresh water fish should be cooked whenever possible for they may contain flukes and other parasitic worms harmful to man. Salt water fish are generally free of harmful parasites.

In populated parts of the tropics, cholera, typhoid fever, and dysenteries can be contracted from eating raw foods handled by the natives. Flies carry the above diseases, too, and are more dangerous in native villages than in the open country. Protect your food from flies. Sterilize it by cooking.

### VITAMIN DEFICIENCIES

When living off the land or sea, there is often little choice of food. If the diet is restricted to a few foods over a period of at least a month, vitamin deficiency diseases are likely to develop. Under extreme conditions, especially at sea, there is nothing you can do but grin and bear it.

Although these diseases are painful and appear serious, they disappear almost miraculously when you reach land and get fresh fruits and vegetables.

Vitamin deficiencies often occur through ignorance where proper food is available. You cannot live on lean meat alone, but you can remain active and healthy for long periods on fat and lean meat. Stefansson lived entirely on meat and fat for a year.

Vitamin A—Vitamin A deficiency causes night blindness, followed by extreme muscular weakness, and in late stages, blindness. Carotene, which supplies vitamin A, is found in yellow fruits and vegetables. Vitamin A in pure form is found in fat, egg yolk, liver, and in oily fresh and salt water fish.

Vitamin B<sub>1</sub> or Thiamine—Absence of vitamin B<sub>1</sub> causes fatigue, headache, and finally beriberi. Vitamin B<sub>1</sub> occurs naturally in egg yolks, grains, and lean meat.

Vitamin B<sub>2</sub> (Riboflavin)—A deficiency of this vitamin causes irritations of the digestive tract. It is found in a wide variety of foods, such as lean meat, liver, eggs, grains.

Vitamin C—Scurvy is the result of a deficiency of this vitamin and is characterized by irritability, lethargy, soreness and stiffness of the joints, loosening of the teeth, nosebleed, and hemorrhages under the skin. Vitamin C

is abundant in liver, citrus fruits, green vegetables, and wild herbs such as sorrel, purslane and dock.

Vitamin D—Vitamin D deficiency causes rickets. This vitamin is produced in the skin by sunlight and is found in liver oils.

Pellagra is a vitamin deficiency disease caused by a lack of vitamin B<sub>1</sub> and complicated by other dietary deficiencies. It is characterized by skin lesions, digestive disturbances, nervousness and paralysis.

If the symptoms of any vitamin deficiency diseases should appear, make a special effort to vary your diet. An adequate supply of vitamins can generally be obtained by eating a variety of foods. If you manage to survive for a month on land, the chances are you have eaten enough different kinds of foods to keep yourself supplied with all the necessary vitamins. If any of the above symptoms are showing, get busy and experiment with some new foods. Green grass contains vitamins A, B, and C. Try it.

## CHAPTER VII

### Shelter

The ability to provide yourself with adequate shelter will increase your chances of surviving and greatly reduce your physical hardships.

*Shelter and sleep are as necessary to a stranded man as food and water. You will tire as quickly from loss of sleep as you will from lack of food.*

When lost or stranded, decide what you need to make you safe and comfortable for the night, and then look for these things. Avoid the things that are most likely to prevent a good night's sleep. In a strange country begin to look for a site at least two hours before sunset; don't wait until dark. Consider these factors in selecting your camp:

FIG. 169. A Natural Rock Shelter and a Leaf Bed—A Little Ingenuity Will Give You Additional Protection from Wind and Rain

1. Available food.
2. Good drinking water.
3. Enough level ground for your bed.
4. Protection from wind and storm.
5. Bedding and shelter material.
6. Protection from floods, wild animals, rock falls, high tides, wind and cold.
7. Concealment from enemies.
8. Absence of insect pests.
9. Firewood.

#### *Natural Shelters and Windbreaks*

Make camp with the least possible expenditure of time and energy. A ravine or narrow valley between steep hills collects cold, heavy air at night

FIG. 170. Windbreak Shelter

FIG. 171. Tarpaulin Shelter

and will be several degrees colder than the surrounding heights. A natural terrace, a clump of bushes, a small depression, or a large rock on the leeward side of a hill will break the wind and make a comparatively warm site.

When you find your site, examine it well. Rocky crevices and caves may harbor poisonous snakes; hollow trees and logs may contain ticks, mites,

FIG. 172. Parachute Tent Pitched High to Give Room. Use Rest of Chute for a Blanket

FIG. 173. Parachute Tent Pitched Low to Make Floor. Pile Leaves Under Floor for Bed. Waterproof and Camouflage by Covering with Overlapping Leaves, Branches, or Bark

scorpions and stinging ants. The time you spend making yourself comfortable for the night will pay good dividends the next day.

### **Brush Shelters**

With a little time and effort a brush shelter can be made of two poles leaned against a log and covered with boughs or palm fronds. A more elaborate lean-to can be built. (Figure 175.) Tie cross pieces to the uprights with

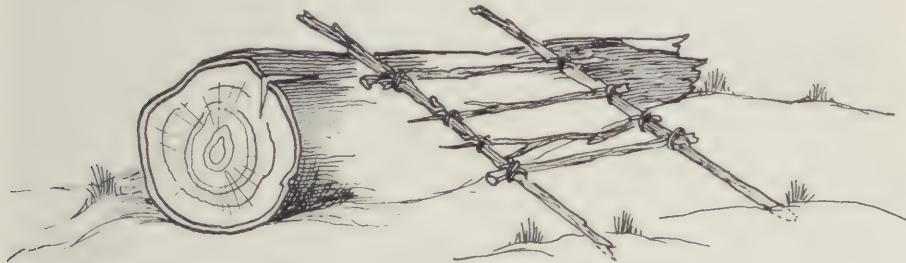

FIG. 174. Log Shelter

FIG. 175. Lean-to

vines or bark. Cover the frame with evergreen boughs, elephant grass, palm, or banana leaves, or strips of bark depending upon the available foliage. Start the boughs at the bottom row and work up shingle-fashion. A section of your parachute makes a good tent when pitched as shown in Figures 172 and 173. (See diagram, Figure 180.)

### **Snow Shelters**

*In a cold climate the primary purpose of a shelter is to break the air movement and retain the heat from your fire or body. The shelter should be small, windproof, and as nearly closed as possible. The smaller the air space around*

your body and the less the air circulation, the warmer your shelter will be. A snow cave meets the above requirements and is easy to construct. Select a spot where the crust is firm or where the snow covers low-hanging evergreen boughs. Scoop or kick a hollow beneath the crust or limbs. (Figure 181.)

If you build a fire, there will be danger of carbon monoxide poisoning

FIG. 176. Plaiting a Palm Leaf ("Yank")

so a more open shelter is necessary. Dig a trench in a low drift or bank. Line the floor and roof the trench with boughs. Build a fire at the entrance and reflect heat inward with a reflector of logs, boughs or snow blocks.

Make the roof strong to support a layer of snow. This will help hold the warm air in. If you do not have a fire, cover the entrance and don't worry about air. You will get plenty. If you insulate your body from direct contact with the snow and prevent circulation of air, you will keep warm.

FIG. 177. Snow Bank Shelter

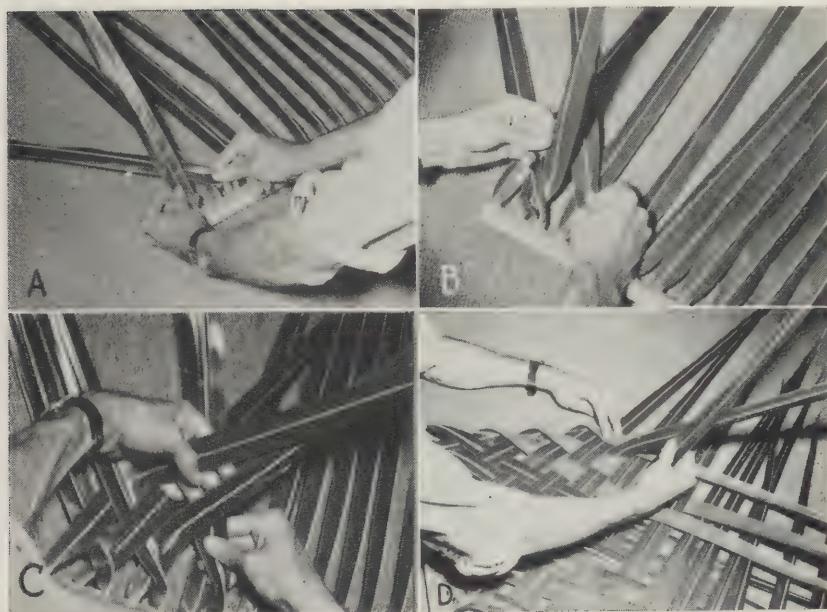

FIG. 178. Thatched Palm Leaves Make Excellent Water-repellent Shelters and Comfortable Beds

### Desert Shelters

In desert country you are concerned with protection from sun and heat, although wind is an important factor and cold often becomes disagreeable at night.

In the early evening, desert sand may be so hot you can't sleep on it, yet after dark the desert becomes chilled. To insure a maximum of warmth throughout the night, spread a coat, parachute, or blanket of vegetation over the ground while it is still hot. This prevents the rapid radiation of heat and will help keep you warm through the night.

Natural shelters such as vegetation, overhanging rocks, and depressions will offer shade, provided you shift with the sun. A cave or covered trench is practical where the sand or soil is loose.

### Beds

*A good bed serves two functions; it allows the body to relax completely and it insulates against ground chill. To do this it must be dry, smooth, soft and free of insects.*

*Warmth.*—A cold man can't relax. He will wake up more fatigued than when he went to bed. The ground is cold at night and conducts body heat away. To sleep warm you need more insulation below than above you as the ground is a better heat conductor than the air.

If it is cold and there is no snow, the ground chill can be removed by building a large fire over the spot you intend to sleep on. Spread the coals and stamp them into the ground; then make your bed over the heated area.

In the open, several fires with reflectors may be necessary to keep you warm.

*Smoothness.*—Hard, level ground is more comfortable than soft, uneven ground. Avoid hummocks, small depressions, sticks and small stones.

Sand feels soft but is really hard, and if you are restless it soon becomes very uncomfortable. To make a good bed, scoop out hollows to fit your body contours, especially the hips.

*Level surface.*—Don't sleep with the head downhill. A level surface is best, but a slight slope will do. Too steep a slope will cause sliding and rolling.

*Dampness.*—Dampness is a problem in tropical forests during the wet season. It can be overcome by sleeping off the ground.

A dry jungle bed can be constructed as in Figures 183 and 184. Two logs five to twelve inches in diameter can be substituted for the uprights.

A hammock or platform can be made from vines and leaves or a parachute. The same section used as a tent can be doubled and hung as a hammock.

*Insect pests.*—A smudge produced by burning wet or green wood, leaves, or grass will help keep mosquitoes and flies away.

FIG. 179. Parachute Hammock—Swing Hammock with Shroud Lines

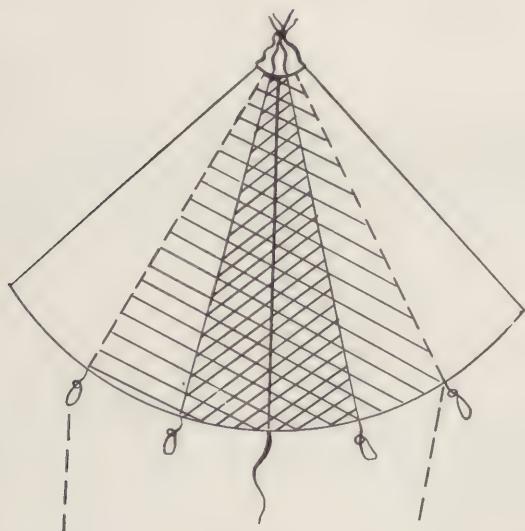

FIG. 180. Diagram for Cutting Chute to Make Tent and Hammock. Cut Out Four Sections as Shown by Dotted Lines. Fold Double to Make Hammock.

FIG. 181. Snow Tunnel Shelter

FIG. 182. Bough Bed (Laid)

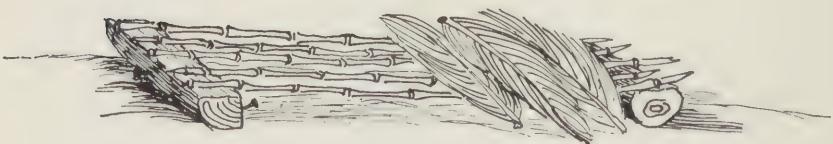

FIG. 183. Jungle Bed

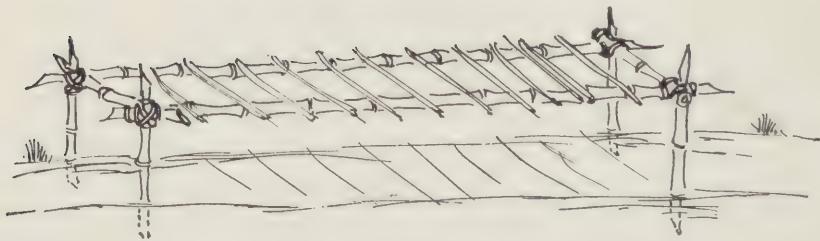

FIG. 184. Jungle Bed

Any place free of flies and mosquitoes, no matter how uncomfortable otherwise, will be acceptable. The only real protection against mosquitoes is a net. (See pages 189-193.)

### ***Bed Construction***

Grass, sedge, dry leaves or boughs are all good bedding material. Balsam, spruce, or hemlock make the best bedding in cold climates. Such beds must be properly constructed to give a maximum of insulation and comfort.

Insert the branches in the ground with the tips leaning all in the same direction and with the under or curved surface downward. Plant rows the length of your bed about six to eight inches apart. Cover with fine feathery tips.

FIG. 185. Bough Bed (Inserted)

### ***Water Proofing***

Keeping yourself and equipment dry is a major problem in the tropics. A very good waterproof fabric can be made from the broad leaves of young banana trees. Build a hot fire on a flat stone or a platform of small stones. When they are well heated, rake the coals off and place banana leaves one at a time on the hot stones. Let the leaf remain for a minute or two until it turns darker and becomes glossy. The heat "rubberizes" the leaf, making it more pliable and water repellent. The leaves will last for some time and can be used to shingle a lean-to, make a ground cloth, crude poncho, or a wrapper for matches, food, and other small articles.

## CHAPTER VIII

# Survival in Special Areas

Wherever or whenever conditions are exceptionally adverse, survival will be dependent upon specific information. The more you know concerning a particular area or set of conditions, the longer your survival time will be.

### OCEAN SURVIVAL

Survival on the ocean depends to a large extent on the rations and equipment you have with you, the use you make of them, and the degree of skill, ingenuity, and resourcefulness you employ. The Navy, Coast Guard and Merchant Marine have equipped all life boats, rafts and planes with survival

FIG. 186. Eighty-Three Days on a Raft

FIG. 187. Rescue After Existing Nearly Three Months on the South Atlantic

equipment adequate for emergencies at sea. Know where this is stored in your raft or plane before the need for it arises. Check your equipment before starting out on a mission, and know how to use it. Take care to see that fishing tackle is included. Fish may be your only source of food and water. Under severe conditions of cold or heat, clothing becomes as necessary as water or food. Be dressed for the emergency and take extra clothing with you when you abandon ship. Before leaving, drink all the extra water you can. Your body is a good storage tank. Many useful articles can be made from a canvas tarpaulin if you take it along. As soon as you are adrift, make inventory of such articles as safety pins, campaign bars, knives, and military

insignia, and save them for future use. The most useless appearing articles may be put to practical use when the going gets tough.

*Survival without equipment depends more on fresh water than on food.* Without water, a man in good health will become delirious in about four days, death will occur in from eight to twelve. If you have water and are in good health you can live without food for as long as 21 days. Survivors have been known to live for 10 days or more on as little as two or three ounces of water

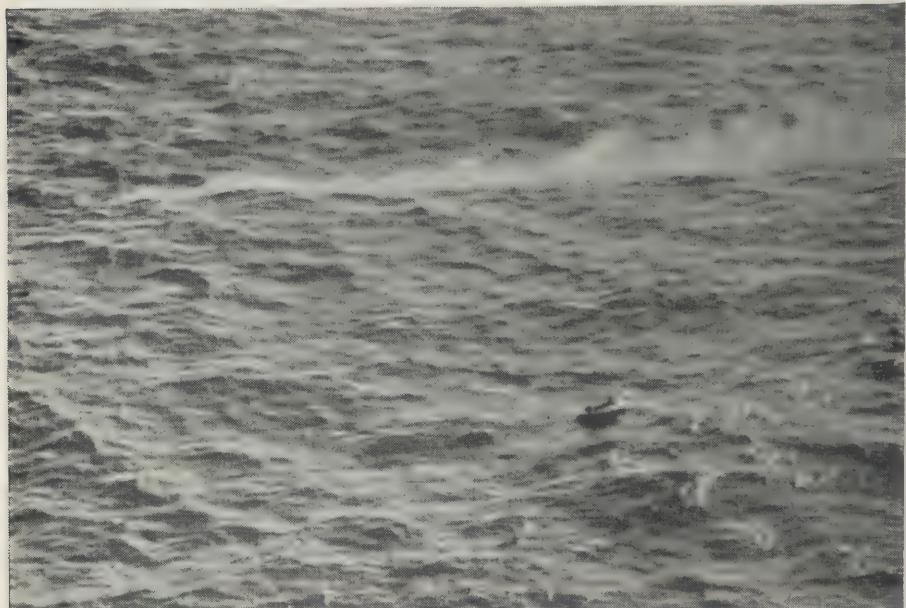

FIG. 188. Downed Fliers Release a Smoke Signal (British Combine)

per day without causing any apparent bodily damage. *The amount of water and food you need depends upon weather conditions, physical exertion, and individual resistance.*

The record for survival at sea was set by a Chinese seaman who drifted 133 days in the Atlantic. He subsisted on fish and rain water, and was able to walk ashore when rescued.

#### ***Living Without Food or Water***

*If you lack water, don't eat. Your body uses up water in digesting and assimilating food, and the elimination of the waste products also draws water from the tissues.* Abstain from both food and water for the first twenty-four hours. After that, ration what you have; and when that is gone, live off your body fat and protein. When these are converted to energy, water is released by the tissues and will help to maintain kidney activity. Keep your body protected as much as possible from sun and wind, since heat and air movement

increase evaporation. Heavy clothing in warm weather, strenuous exercise and worry induce sweating with a subsequent loss of water.

One pound of body fat will provide your system with an equivalent of two good meals. The rate at which body fat and protein is converted to heat and energy will depend on the air temperatures and your activity and mental state. *You can live longer on your stored energy by relaxing mind and body and guarding against exposure to extreme temperatures.*

When taking little or no food you can't expect a bowel movement. It is nothing to worry about and you don't need any treatment for this condition.

### **Water**

*Rain, ice, and the body fluids of animal life are the only sources of water. Don't drink sea water; it will only aggravate your thirst and increases water loss by drawing body fluids from the kidneys and intestines, eventually resulting in serious convulsions and delirium. You will have some difficulty in passing urine when you are not drinking much, and the urine you do pass will be dark and thick. Don't worry. Such a reaction to dehydration is natural. Urine contains waste products from the body and may be almost as concentrated as sea water. Drinking it will only increase thirst and draw water from the body tissues.*

Water evaporates through the skin. Some survivors have reported that by remaining in the sea for hours at a time they prevented the evaporation of water from their bodies and even absorbed enough to increase kidney activity. *The blood of birds and the blood and body fluids of fish are drinkable and nourishing if chewed out. Break the back bone and drink the spinal fluid.*

Collect rain water in any available receptacle, using clothing, parachute, or sails. Devise methods before there is an actual need. If the shower promises to be light, take measures to get every drop of water. Wet your cloth or canvas catchment in the sea so that fresh water will not be absorbed by the fabric.

The amount of salt water contaminating the rain water will be negligible, but the amount of fresh water lost through absorption if you fail to first wet your canvas will be considerable. In a driving rain, a piece of canvas or any large flat surface held at an angle to the wind will catch the water. Your body can store water, therefore drink all you can hold when water is plentiful. Little of the water taken in large quantities when you are dehydrated is lost through perspiration or excessive urination.

### **Food Getting**

The condition of your body will determine whether or not you can or will eat starvation foods. *The sea is far richer in different forms of life than the land or fresh water, and if fresh water is available there is little danger of starving to death. The problem is to tap this wealth of food. No one at sea*

*should be caught without fishing tackle on his person at all times, but even if this happens the situation is far from hopeless.*

### Fish

*Fish caught at sea are good to eat, cooked or raw. Not any of them are likely to be poisonous.* Flying fish are widely distributed, palatable, and probably are the most available source of food if you have no equipment. Many survivors have lived on them alone. In time some may glide into your boat or against it.

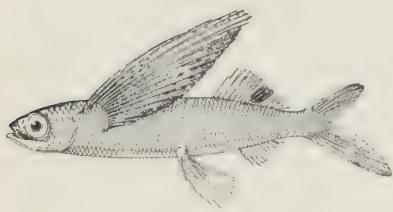

FIG. 189. Flying Fish

At night they are attracted by a light, become helpless within its radiance, and can be scooped in a net. Shine your light on the side of your boat or on any surface that will reflect it and the flying fish will often glide toward the light and in or against the boat.

The heart, liver and blood of fish are good to eat, though in some fish they

are less palatable than the flesh. Intestinal walls are edible, but the contents may be dangerous unless cooked. The stomachs of large fish may contain small fish partly digested; they are excellent. Fish eyes contain a high percentage of water.

Small fish can be caught with a skewer or gorge hook made of wood or metal and a short line improvised from shoe laces, canvas or clothing. If you have hook and line, but no bait, a strip of leather cut from the tongue of your shoe, a button, or a piece of canvas fastened to the hook and trolled behind your boat may prove effective. It must be kept moving so as to resemble a small fish.

If you have a knife you may be able to stab large fish near the surface, or spear them by tying your knife to the end of an oar. Slash with your knife in schools of small fish. Natives get bait in this manner.

Fish spoil quickly in warm weather; therefore clean and eat them without delay and immediately dry what is left. If the sun is hot, fish can be partially cooked by cutting them into thin slices and placing them on a dry metal surface.

### Fishing Line

To make a fishing line cut a piece of canvas about a yard square, being careful to follow the weave of the fabric so the threads or ravelings may be drawn. Be sure the canvas is dry; wet canvas is difficult to unravel. Place 8 or 10 strands between the thumb and forefingers of each hand and roll or twist the thread clockwise, at the same time passing the right hand over the left counter-clockwise. This will form a small rope with a breaking point well

over 100 lbs. When about 18 inches of line is completed, cut off the strands at intervals of about two inches so that each thread will be progressively longer. As the end of each strand is reached, feed in a new strand, until 50 or more feet of line have been made.

A two-strand line when made as described will have a breaking point well over 20 pounds.

Fabric from clothing can be utilized in the same way.

### *Fishhooks*

Fishhooks can be made from wood split from seat benches or gunwales. Shape the shaft and cut a notch near the end in which to seat the point.

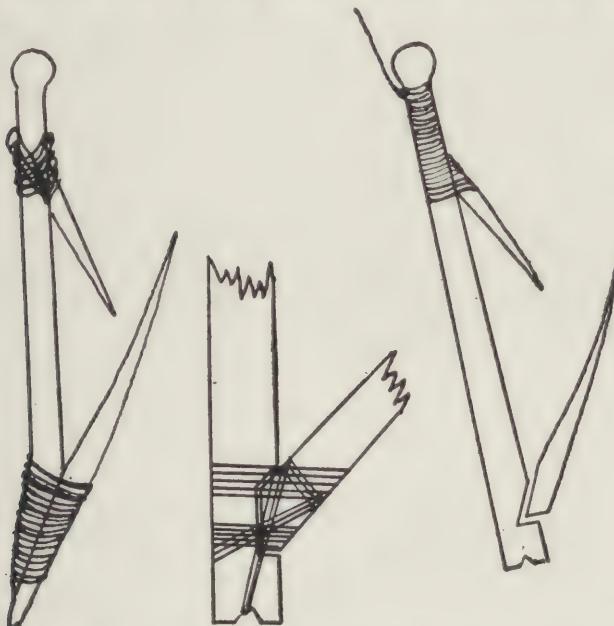

FIG. 190. Construction of Wooden Fish Hooks

Sharpen the point so the hardest part of the grain will form the extreme tip as well as the barb. This section should form an angle of about  $30^{\circ}$  with the longitudinal axis of the shaft and be lashed firmly in position, using single strands from the canvas. Make the line fast by binding it tightly to the shaft. (See Figures 190 and 191.)

### *Bait Grapple*

A grapple for collecting and pulling in seaweed can be made from four heavy slivers of wood cut from a raft or boat. Cut three notches near the end of the heaviest sliver of wood in which to seat three pieces and lash them in position. Make the line fast to the shaft by cutting three or four notches near the end and lashing it tightly with canvas threads. (See Figure 192.)

FIG. 192. Bait Grapple and Container. A—Wick; B—Grapple; C—Fish Spine Needle

#### Bait

Small forms of life drifting about in the sea furnish food directly or indirectly for all the larger forms of aquatic life. This drifting life is most abundant in northern seas, and in some areas is so dense that it colors the water. It can be gathered with a tow net or improvised dip net. Use the small creatures as bait for fish, but don't eat them as they are salty and contain sharp spines that will injure the stomach and intestines. Likewise, don't eat jellyfish; they possess stinging cells that are poisonous. (For poisonous fish see pages 150-152.)

#### Containers

Containers that will serve as water or fire buckets can be made with an improvised needle and some canvas. If the bucket is to be watertight the

seams must be reinforced with a narrow canvas binding and calked with fish slime that is then allowed to dry into the seams. A seamless watertight container can be made from canvas as described on page 114, Figure 164.

The tail-half of a fish carefully skinned back, then scraped, stuffed with seaweed or rags and dried in the sun will make an oil or water container. Leave the tails and fins attached to the skin. The air bladder of large fish can be dried and used in the same way.

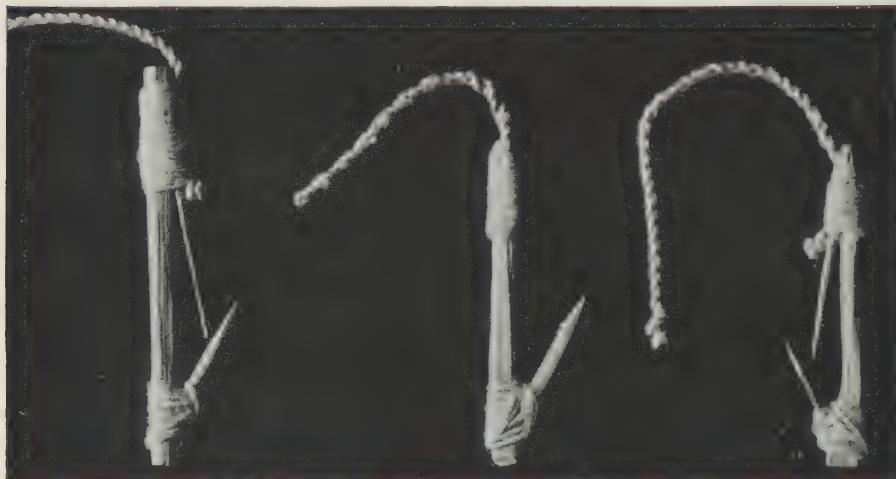

FIG. 193. Wooden Shafted Hooks with Wood, Fish Spine, and Shoe Nail Barbs.

#### **Fire Pots**

The bottom of a canvas fire pot should be kept wet; the sides will act as wicks and prevent the pot from burning. Rags, a few seat shavings, and the oil from fish livers should be saved and lighted as a signal to attract rescuers. Extract the oil by placing the fish livers in the sun. A wick can be made from the canvas threads. (See Figure 192.)

#### **Fishing at Sea**

Your success with fishing equipment will depend on how you use it. Remember the following.

1. Never fasten your line to something solid; it may snap when a large fish strikes.
2. Try to catch small fish; large ones may destroy your tackle.
3. Fish are more apt to see and strike a moving bait than a still one.
4. Use part of any bird or fish you catch for bait. It need not be fresh. Bird intestines threaded on a hook are excellent.

5. Many species of fish are confined to certain depth zones by light, pressure, and food. Some range through a wide variety of depth zones while still others migrate from zone to zone at different times of the day. Try fishing at different times of the day and night at all depths. Don't give up; sea life is not evenly distributed; sooner or later you will have luck.
6. When you hook a large fish, keep a taut line and play him. Don't force him, you may break your line or tear the hook loose.
7. Watch for schools of fish breaking water. Schools of small fish are good indications of the presence of large fish and vice versa. Birds often follow schools of small fish.
8. Many species of fish and drifting sea life come to the surface of the sea at night. Fish shallow and use a drag net.
9. Many small fish are attracted by shade. Lower the sail or tarpaulin into the water; fish may gather under it.

### *Seaweed*

Raw seaweeds are tough and salty, absorb water from the intestines, and are difficult to digest. Eat them only if you have plenty of water. Small edible crabs, shrimp and fish inhabit the seaweed along the coast and patches of sargasso weed far at sea. A grappler dragged behind the boat will collect seaweed. Shake it vigorously and examine carefully as the crabs, shrimp and fish will be well camouflaged in it.

### *Birds*

All sea birds are edible and nourishing, though they may have a fishy flavor and musty odor. Birds are relatively scarce on the open sea, but along coral islands and mid-ocean rocks thousands may be found. Three members of a torpedoed merchantman survived 83 days on a raft catching 25 or 26 birds during that time.

The number of birds you can expect to see on the open North Atlantic is comparatively small. In the North Pacific Ocean most of the seabirds are found near the coasts. Many tropical sea birds breed throughout the year and eggs and young can be found at all times. In the southern oceans many species of birds may be seen and caught hundreds of miles from shore. Land birds migrate miles over water; they often alight on boats to rest and at such times exhibit little fear of man.

Gulls, albatross, terns, gannets (boobies) can be caught by dragging a baited fishhook behind a boat, or lured within shooting distance in the same manner. A flat sharp-edged, triangular-shaped piece of metal or shell, dragged behind the boat will attract gulls and albatrosses. A shiny or colored object is most

effective and a bait of fish or intestines adds to its attractiveness. The bird dives, seizes the lure, and the sharp points catch in its bill and hold fast.

Gannets once settled on a boat or raft will often allow themselves to be captured without attempting to fly away. If they are shy they may be caught in the following manner: Tie a knot with two pieces of line as illustrated in Figure 194, fastening two of the free ends of the knot to the boat. Place some fish entrails or similar bait within the loop. When a bird is attracted to the food, pull the knot together about its legs. A simple overhand knot can be used for the same purpose. Whatever bird you catch, use all of it. The smaller feathers can be used to make a fly or lure. A spinner can be fashioned

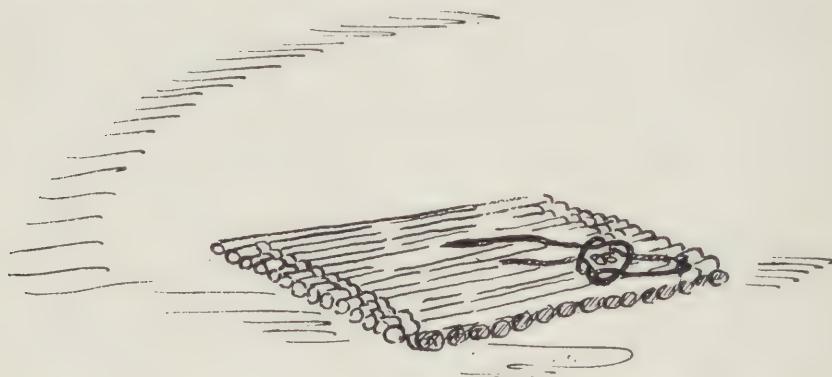

FIG. 194. Bird Noose

from the long plates of the bill. The bones can be utilized for skewer or barbed hooks and the quills stripped to make string. The skin is highly nutritive, but if warm clothing is the pressing problem, skin the bird down the back, dry in the sun and use the thick downy breast feathers for a cap, ear muffs, scarf, or shoe lining.

#### *Indicators of Land*

*Large numbers of birds indicate some kind of land nearby.* Most of the tropical sea birds do not range far from their breeding grounds. This is particularly true of the "boobies" or gannets which are found throughout tropical seas within fairly close proximity to land. Their habit of diving into the sea from a height of 60 or 100 feet is in itself a characteristic almost sufficient to distinguish the bird as a gannet. The only other sea birds which dive from the air are the brown Chilean pelicans, also seen close to land (within 25 miles) and the much smaller terns and the long tail-feathered tropic birds which may or may not be far from land. Note the evening flight of sea birds, for in some species it will be a reliable indication of the distance and direction of land. Frigate birds are easily distinguished from any other

FIG. 195. Gull

FIG. 196. Brown Booby

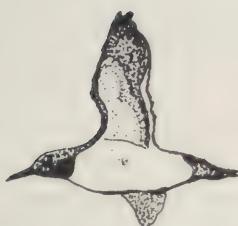

FIG. 197.  
Horned Puffin

FIG. 198. Murre

FIG. 199. Frigate Bird

sea bird, and they never sleep on the water. When you see them in the evening, you can be reasonably sure that land is not over fifty to seventy-five miles away. Gulls, with but a single exception, are birds of the shore lines and are not found in the open ocean. In northern seas, especially in the Bering Sea, adjacent parts of the North Pacific Ocean, and in parts of the North Atlantic and Arctic Seas, various species of auks are a good indication that land is near. The very distinctive tufted and horned puffins and the common murre are generally seen within 75 to 150 miles from land respectively and their flight at dawn and dusk shows the direction of land. (See Figures 195 through 199.)

Fixed cumulus clouds in an otherwise clear sky are likely to have been formed over high or mountainous land. Take note of any stationary cloud especially where moving clouds are passing by, for it is an indication that land lies beneath it beyond the horizon. Lagoon glare, a greenish tint in the sky or on the under side of a cloud, is caused by the reflection of sunlight from the shallow water of coral reefs. The reflection of light from any surface such as sand, shoal water, ice or snow may be reflected in the sky or on clouds and is an indication of land. Drifting wood or vegetation is an indication that you are approaching land.

### ***Morale***

High morale will bring you through. Without it you may fail. Living without equipment in an open boat on the high seas is the severest test of morale. Don't let your thoughts and imagination become your greatest enemy. Keep fishing and experimenting to the limit, for activity is the best cure for depression.

Remember:

"Life's battles do not always go  
To the stronger or faster man,  
But sooner or later the man who wins  
Is the man who thinks he can."

## **THE SEASHORE**

### ***Where and What to Hunt***

The sea beaches and shores of the world contain more easily-available wild food than any other division of the earth. If you are stranded on the seashore in a warm climate you should have little difficulty sustaining yourself indefinitely.

Types of oysters, mussels, scallops, crabs, lobsters, shrimps and prawns are found along all seashores. At low tide, start hunting on the beach by turning over the stones nearest the low tide level and examine crevices and sheltered nooks of rocks. Examine the sand and the line of sea detritus that marks the level of the high tide. *The best hunting will be in the shallow water below*

FIG. 200. Three Pacific Fleet Airmen Who Survived 34 Days on a Tiny Rubber Lifeboat

*the tidal zone and in the tidal pools.* Some of the animals which inhabit rocky shores, stony beaches, or sand and mud in one area may be looked for anywhere in the world under similar physical surroundings. They may differ in genera and species, but a picture of typical forms is a sufficient guide to their recognition.

The outer margins of rocky or coral reefs usually contain channels, and on the surface of the reefs are pools that contain edible sea life. On sandy beaches you can expect to find bivalve mollusks and sand crabs. The loose, soggy soil of salt marshes and mud flats is the home of fiddler crabs, the mud snail, and various other types of mollusks and crabs.

FIG. 201. Blue Crab

FIG. 202. Hermit Crab

Crabs also inhabit mangrove swamps throughout the tropics. Some live in holes in the mud, others burrow under the mangrove roots. Still others live among the trunks and branches. In all these swamps, oysters, barnacles and mussels are found fastened to the mangrove roots near the water line and in the mud.

Oysters and fish are numerous at the mouth of mangrove rivers and streams. Catfish are often plentiful, but the most abundant fish in such areas is the mud skipper. It is small but edible, and will be seen out of water on rocks, limbs, roots and mud banks. On the mud flats at the seaward edge of mangrove swamps, small rays and sharks may be speared as they come in with the tide. The wings or flaps of the ray may be cut off and eaten. Mullet and larger fish can be speared or netted. Birds such as ibis, egrets, herons, flamingoes and ducks are generally present in great numbers.

Be careful in traversing a mangrove swamp. Wait for low tide. (See page 28)

Some fish can be obtained best at night. They swim near the surface close to shore reefs. By remaining still you can hit them with clubs or spear them. In shallow lagoons, mullet and other bottom feeders can be spotted with a torch and speared or slashed with a machete.

In daytime at ebb tide the larger fish can be shot as they swim over the

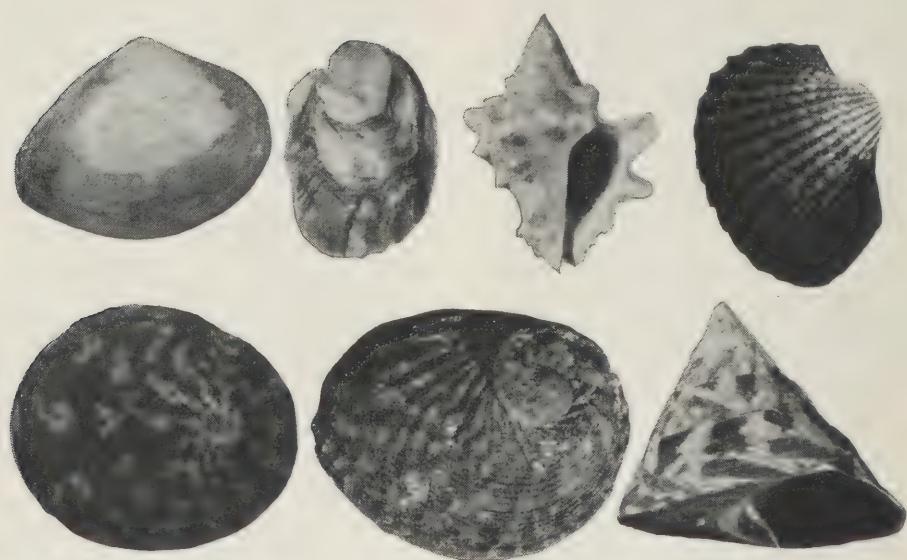

FIG. 207. Some Common Edible Marine Mollusks of the Southwest Pacific

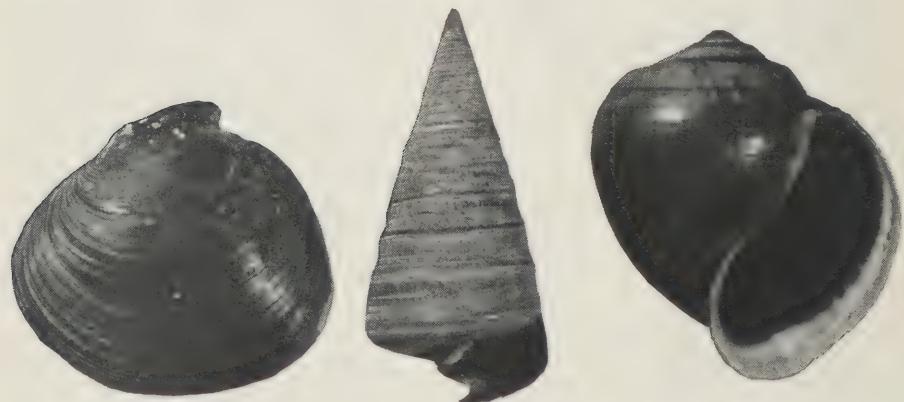

FIG. 208. Some Edible Fresh Water Mollusks of the Southwest Pacific  
(Smithsonian Institution)

FIG. 209. Some Edible Marine Mollusks of Alaska and the Northwest Pacific

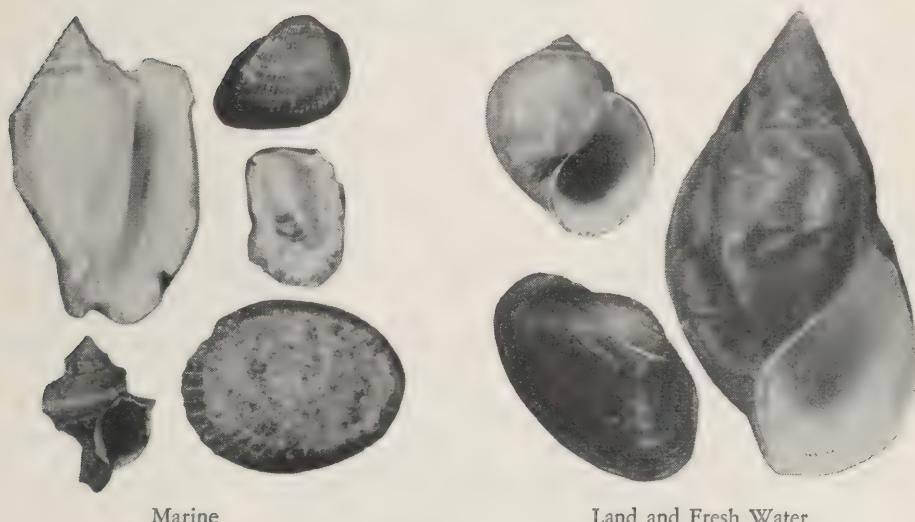

FIG. 210. Some Edible Mollusks of Africa (Smithsonian Institution)

reefs with their backs out of water. They frequently swim into the pools on top of the reefs at high tide and can be trapped there by building a net across a channel through which they must leave when the tide falls. A seine of coconut leaves is useful for driving fish into a trap. Stingrays and flounders lie in shallow water where they are difficult to see but easy to spear. (See page 209.)

Crabs and lobsters may be speared, can be caught with the hands, bait-trapped, or caught with a scoop net. They are most active at night and should be hunted in shallow water along the beach. As far as is known, all crabs and lobsters, whether fresh water, marine or land forms, are edible. Salt water crabs can be eaten raw, but all fresh water and land crabs should be cooked.

Marine shrimps and prawns may be found anywhere in shallow water, but they prefer rocky coasts and reefs. They can best be captured with a dip net.

Salt Water Shrimp

Marine mollusks, such as oysters, clams, scallops, welks, periwinkles, barnacles and conches, form a large part of the food supply of natives all over the world. Along many shore lines the supply is practically inexhaustible. They can be gathered by simply walking

along the beach and picking them up. They can be eaten cooked or raw. Shifting bottoms, sedimentation, rough water and swift currents generally constitute unfavorable environments for oysters, clams and scallops. Hunt them in sheltered coves, lagoons, tidal pools and crevices. Snail types are found chiefly on rocky shores or under coral blocks and slabs of stones, while most of the bivalve mollusks will be found buried beneath the surface of sand or mud. Many mussel-type (bivalve) mollusks live in burrows or holes in muddy or sandy bottoms and must be found by digging. Some will be deep, others shallow. Some types, such as the razor clam, can burrow faster than a man can dig. If you can't locate burrows, watch for squirts of water or bubbles from beneath the sand or mud and dig there. Oysters are found largely in shallow water.

The sea cucumbers found on almost all rocky shores and reefs are edible, raw or cooked. Strip out the long muscles on the inside of the body.

Spiny, globular sea urchins of temperate and arctic shores are harmless to handle and the eggs within their bodies are edible, but the needle urchins of tropical shores have long spines that will penetrate the flesh. One species contains poisonous glands.

### **Dangerous Mollusks**

There are only two groups of mollusks that should be avoided. These are the cones and the terebras. They have poisonous teeth and their bite can be fatal. They are distributed principally throughout the tropical and subtropical

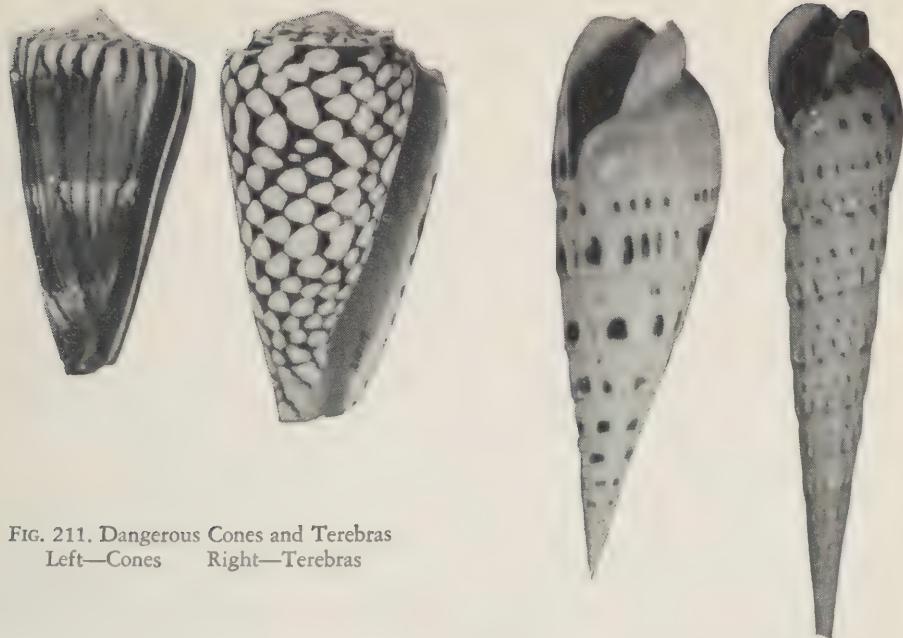

FIG. 211. Dangerous Cones and Terebras  
Left—Cones Right—Terebras

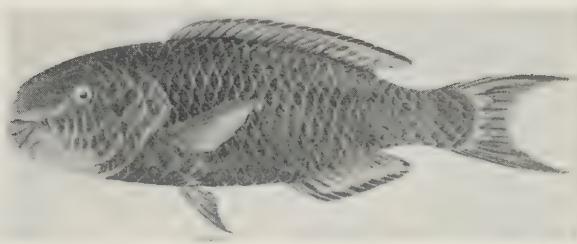

FIG. 212. Parrot Fish

FIG. 213. Trigger Fish

FIG. 214. Pufferfish

FIG. 215. Porcupine or Spiny Pufferfish

shores of the world, but are nowhere common, and they are easily recognized.

In the north pacific area the black mussels living on exposed reefs at low tide are occasionally poisonous, though normally edible. The poison is derived from a tiny one-celled protozoan on which the mussel feeds.

### **Poisonous Fish**

Some fish are poisonous to eat because of:

- (1) Poisonous alkaloids within their bodies.
- (2) Poisonous foods they have eaten.
- (3) Bacterial decomposition.

Most of the information concerning fish poisoning is not based on scientific study and there are no steadfast rules to go by. It may safely be stated that the danger is greatly exaggerated but you should nevertheless take precautions by following local native customs concerning nonedible fish.

The principle symptoms of fish poisoning are nausea, vomiting, diarrhea, itching, cramps, paralysis and a metallic taste. The symptoms appear suddenly, from one to six hours after eating. No antidote is known and the poison is not destroyed by cooking. Such sickness is not to be confused with the far more common fish poisoning caused by bacterial decomposition which may be destroyed by cooking. In either of the above cases, as soon as the symptoms appear, drink sea water and force yourself to vomit.

Poisonous fish are seldom if ever found in the open sea, but shore forms such as pufferfish, porcupine fish, trigger and parrot fish possess toxic substances in their flesh. All these occur around rocky or coral reefs and muddy or sandy shores. *Do not eat any of the puffer or porcupine fish, as practically all are poisonous.* These fish do not have true scales. Their bodies are covered with smooth skin or by a rough shagrin, or bristles or spines. The gill openings are short oblique or vertical slits. By inflating themselves with air they become balloon-like, hence their name of puffer or balloon fish. (Figures 214 and 215.)

Many of the trigger fishes are brilliantly colored. All have a sharp dorsal spine, scales that do not overlap and the eyes set very far back. (Figure 213) They can be caught easily but none are desirable as food. The striped trigger fish is common in the Southwest Pacific.

In certain seasons of the year in localized areas the red snapper and parrot fish around tropical islands are said to be poisonous, and these should be eaten sparingly until proven to be nontoxic. It is thought that these fish become poisonous by eating poisonous marine organisms or plant-like growths around these islands. Parrot fish have true scales and their mouth is formed of long plates resembling the beak of a parrot. (Figure 212)

In certain regions large barracuda have been reported as poisonous, but this was probably ptomaine poisoning.

*All the fish along the shores of the North Pacific and in the Arctic Ocean are good to eat. No poisonous varieties are known. The eggs of some sculpins are deadly poisonous. Therefore don't eat any fish eggs found in clusters or clumps on rocks, logs or reefs.*

In addition to the abundant sea food, the seashore provides birds, mammals, drinking water and many edible plants. It should be quite evident that the seacoasts of the world offer a wide variety of foods and that this is particularly true of the tropics. No equipment is essential, but the task of surviving becomes a hundred-fold easier if you have matches, a head net and machete. Don't get caught without them.

### TROPICAL PLANT FOODS

There are numerous edible plant foods found only in the tropics that may sustain you in emergencies. Because these plants must in most cases be specifically identified before you can make full use of them, only a few of the more common and widely distributed ones are discussed. Try to learn and use these plants before an emergency arises.

FIG. 216. Picking a Pandanus Fruit

FIG. 217. Tropical Jungle (U. S. Marine Corps)

FIG. 218. Celery-like "Millionaire's Salad" from Base of Coconut Palm Crown ("Yank")

FIG. 219. Cutting Bamboo Shoots

Palms are found throughout the tropical world, and are most numerous near the equator. They grow in all types of habitats and vary in form from tall trees to shrubs and vines. The leaves are generally pinnate or palmate, and many, but not all, palms have the well-known leafy crown. Palms are one of the best sources of plant food for inexperienced individuals. They are widespread, conspicuous, and a great many of them contain drinkable sap, edible fruits, buds or starchy cores within the trunks. Palms also furnish alcohol, sugar, oils, fibers, shelter, and clothing material.

*The terminal bud or growing point of most palms is edible either cooked or raw.* It is located on the tip of the trunk, enclosed by the crown of leaves or sheathing bases of the leaf stem. Eat any that are not too bitter.

*The sap of many of the palms is drinkable and nourishing.*

The fruits of palm trees are generally produced in clusters below the leafy crown. The fruits of the coconut, nipa and date palm are excellent food, but the fruits of many other old-world species are not edible. Some contain minute crystals that cause intense pain. *Eat old-world palm fruits with caution. Most of the new-world palm fruits are edible or at least not poisonous or irritating.*

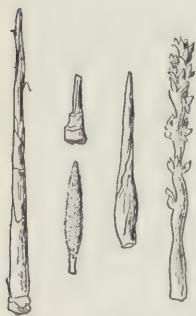

FIG. 218a. Palm Buds

*Enormous quantities of starch are stored in the trunks of some of the palms.* It is edible in all species in which it is found, but is not worth trying to get unless you have an axe or machete.

From this general information it should be evident that in an emergency, or if you lack specific knowledge concerning edible palm species, you can obtain and eat the fruit, sap, starch or buds with reasonable safety and success. A little specific knowledge, however, will greatly facilitate your use of palms for food.

### *The Nipa Palm*

The nipa palm looks like a stemless coconut palm with long leaves rising in tufts from the rootstock to a height of about 15 feet. The short, erect flower stem produces a cluster

FIG. 220. Nipa Palm (*Nipa fruticans*)

of seeds that are edible when young and resemble coconuts in taste. This palm is found growing only in brackish tidal marshes and mangrove swamps of the islands and coasts of the Indian Ocean. The flower stems give off large quantities of an edible sugary sap commonly collected in jointed bamboo funnels. The cabbage is edible and the leaves are one of the best thatching materials.

FIG. 221. Coconut Palm (*Cocos nucifera*)

### **Coconut Palm**

The coconut palm is widely cultivated throughout the tropical world, being common in Africa, tropical America, Asia and the South Pacific Islands. It is usually found growing near the seashore, but sometimes occurs some distance inland. The large terminal bud or cabbage is an excellent vegetable cooked or raw. The nuts furnish meat and water, and a sugary sap can be obtained by cutting the flower spikes. The nuts are available the year round. The jelly-like flesh of half-grown coconuts is more nourishing and can be eaten in greater quantities than the hard oily meat of the mature nuts. A sprouted nut is excellent food. (See palms page 47.)

### *The Sago Palm*

The sago palm occurs on the islands of the Indian Archipelago and the Malay Peninsula in damp lowlands, fresh water swamps and along streams, lakes and rivers. The hard trunk contains an accumulation of starch which is at a maximum when the tree is between the ages of 10 and 15 years, just before the flowers are produced. Lesser amounts exist in immature or flowering

FIG. 222. Sago Palm (*Metroxylon*)

trees. To obtain the edible starch, cut down the tree, split and remove the hard outer shell, and slice the core into small fragments. Boil these or wrap them in leaves and bake. Chew the starch out of the pith. A flour can be obtained by crushing the pith, washing and straining it through a cloth or netting to remove the fiber. The terminal bud may be cooked and eaten.

### *Sugar Palm*

The sugar palm is common throughout the open lands of the Indian Archipelago. It is more abundant in the hilly districts of the interior than on the seacoast. The mature tree is 30 to 40 feet tall with a dense crown of leaves. The terminal bud is considered edible but should be eaten with caution. Starch can be obtained from the trunk. A sugary sap can be collected by cutting the flower spikes. The black fibrous material at the base of the leaf stalk makes excellent cord.

FIG. 223. Sugar Palm (*Arenga*)

FIG. 224. Buri Palm (*Corypha*)

### *The Buri Palm*

The buri palm is a very large fan-leaved palm found only in tropical Asia. The leaves may be as large as nine feet in diameter. The pithy portion of the trunk contains starch, difficult to obtain because of the thick, hard, outer shell. The sap is sugary and the buds are edible. The leaf and leaf stem fibers are used for making cord and rope.

FIG. 225. Piva or Peach Palm (*Guilielma utilis*)

### **Piva or Peach Palm**

The piva palm is confined to regions of tropical America. Its slender trunk, 20 to 40 feet tall, is easily recognized by its alternating light and dark bands of spines. The mature fruits are red or yellow and grow in large clusters. They may be eaten boiled or roasted and they taste like sweet potatoes or chestnuts.

FIG. 226. Bacaba and Patawa Palms (*Jessenia, Oenocarpus*)

#### **Bacaba and Patawa Palms**

These palms are found in the moist forested regions of the Guianas and Brazil. The pulp of the fruit can be chewed and eaten. The oily kernel within the pulp is also edible. The fruit is smooth, dark purplish in color and about three-quarters of an inch long.

FIG. 227. Assai Palm (*Euterpe oleracea*)

### *Assai Palm*

The Assai palm and related species are native to the forests of tropical South America where they generally grow together in large masses. The Assai palm grows in swampy places particularly along the banks of rivers within the tidal limits. It attains a height of 30 or 40 feet with a stem about as thick as a man's arm. When the fruit is mature, the soft purple pulp is edible.

FIG. 228. Rattan Palm (*Calamus*)

### Rattan Palms

There are many species of rattan or climbing palms with smooth reed-like stems seldom more than an inch or two in diameter and usually growing to a great length. Nearly all are native to Asia, being particularly abundant in Malaya and the Southwest Pacific Islands. The leaf stalks are spiny and in many species prolonged through the divided blade into whip-like tails at the end. They are common in the virgin forest. It is safe to try eating the terminal bud of all species. The swollen base of the vine in some species contains edible starch that can be obtained and utilized as described for sago. Drinking water can be drained from lengths of the stem and the stems themselves serve as cord or rope. (See top of page 47.)

### Bamboo

There are many different kinds of bamboo distributed throughout the warmer regions of the world. They are found in open or jungle country in either lowlands or mountains. The young shoots of all may be cooked and eaten, although some species are better than others.

FIG. 229. Bamboo

FIG. 230. Sugar Cane (*Saccharum officinalis*)

### Sugar Cane

The cultivated sugar cane and similar appearing wild species grow throughout the tropical regions of the world, usually in open country along the banks of rivers and streams. Cultivated varieties are commonly found around abandoned plantations and similar dwellings. The sugar content is high and can be obtained by removing the hard outer stem layer with a knife or the teeth and chewing the soft inner pith.

### Bananas and Plantains

Bananas and plantains are found in the tropical and subtropical regions of both hemispheres. They are herbaceous plants in which the leaf sheaths encase the stem. Bananas and plantains look much alike and it is not necessary to distinguish between them. The fruit of both is eaten raw or cooked, although most plantains must be cooked to be edible. The fruits of the different species vary in shape and size. The slender terminal flower bud of some species is excellent when cooked, and the rootstock and leafsheaths of many of them can be cooked and eaten in emergencies.

FIG. 231. Bananas and Plantains (*Musa*)FIG. 232. Taro (*Colocasia antiquorum*)

### Taro

Taro is related to our jack-in-the-pulpit, calla lily, and skunk cabbage. There are numerous species in the Pacific regions, many of which are used by the natives as food. Taro is especially abundant in the Pacific Islands and also occurs in India, Ceylon, the West Indies and Eastern Asia. It thrives best in

damp or wet areas. The roots are rich in starch, though they are pungent and irritating unless thoroughly baked or boiled. The tubers may weigh from one to twelve pounds, and have a mottled bluish-gray appearance. The young leaves are edible if boiled thoroughly in several changes of water.

FIG. 233. Buck Yam (*Dioscorea pentaphylla*)

### Yams

Yams are sweet potato-like vines found throughout most tropical and subtropical regions. The large tuberous roots of cultivated and wild species are dug up by the natives and either boiled or roasted. They grow in jungle thickets and in forests. Some species are poisonous unless properly prepared. The buck yam is common in the jungles and thickets of tropical Asia, including the South Pacific Islands.

**Manioc, Cassava, Tapioca**

The fleshy and starchy root of bitter and sweet manioc yields the greatest portion of the daily food of the natives of tropical America. There are about 50 species and they are most abundant in the wet areas of Peru, the Guianas, Brazil, the Antilles and Southern Mexico. Bitter and sweet manioc, a shrubby

FIG. 234. Manioc (*Manihot*)

plant about six to eight feet high, is the species commonly eaten in South America. It is also cultivated widely in the old-world tropics. The two varieties cannot be distinguished except by taste. Sweet manioc can be eaten cooked or raw, but bitter manioc must be cooked (as directed on page 61) to rid it of poisonous hydrocyanic acid. If in doubt as to whether you have bitter or sweet manioc, play safe: cook it.

**Arrowroot**

The six or seven species of *Tacca* are distributed over tropical America, Africa, Asia and the South Pacific Islands. The various species grow in open country or on sandy or rocky soil near the sea. The carrot-like tubers of all species are rich in starch and are edible when cooked. They should not be eaten raw. (See Figure 236.)

**Seaside Purslane**

One or the other of the seaside purslanes are found on the shores of most tropical countries within the influence of brackish or salt water. They are smooth, succulent plants with fleshy stems and leaves, and salty taste. The entire plant can be boiled and eaten.

FIG. 235. Seaside Purslane (*Sesuvium portulacastrum*)

FIG. 236. Arrowroot (*Tacca leontopetaloides*)

FIG. 237. Wild and Hog Plums (*Spondias dulcis*)

FIG. 238. Figs. (*Ficus pretoria*)

**Wild and Hog Plums**

These are native to the tropics of both hemispheres and the fruits of some of them are edible. The Polynesian wild plum yields a yellowish fruit which tastes something like a pineapple.

**Figs**

Numerous species of edible figs are widely distributed throughout the tropics of both hemispheres. Wild figs resemble cultivated figs and are easily recognizable. The wild figs are usually small and all have a milky juice. Insects are often found in them, but the fruit may still be eaten unless definitely decayed. (See Figure 238.)

FIG. 239. Custard Apple—Sour Sop  
(*Annona muricata*)

FIG. 240. Sweet Sop (*Annona squamosa*)

**Custard Apple, Sour Sop and Sweet Sop**

This genus of small fruit trees is largely represented in tropical America, but various species are widely cultivated throughout the tropics. A wild custard apple is found in tropical Africa and is large, well-flavored and juicy. A similar cultivated species with pale green fruit is found in settled areas of the Pacific Islands. The sour sop is cultivated throughout tropical America and is found both wild and planted in the South Pacific Islands. The leaves are strongly scented when crushed. The spiny green colored fruit is sometimes as large as a man's head. It can be used to prepare a thirst-quenching beverage.

**Stamvrugte and Star Apple**

Members of this genus are found in the tropics of both hemispheres. The star apple is found in the West Indies and Central America, while the stamvrugte is found in tropical Africa on rocky outcrops and mountains. The fruit is red when ripe, about an inch in length, and has a tart flavor. (See Figure 242.)

### Sour Plum

The sour plum is a large, often thorny, shrub or small tree bearing yellow fruits resembling plums. It is found throughout the tropics of America, Asia, Africa and the Pacific Islands, often near the seashore. The genus contains numerous edible species. The pulp of the fruit, but not the seed, is edible.

FIG. 241. Sour Plum (*Ximenia caffra*)

FIG. 242. Stamvrugte (*Chrysophyllum magaliesmonlonum*)

FIG. 243. Breadfruit (*Artocarpus*)

FIG. 244. Screwpines (*Pandanus tectorius*)

### Breadfruit

There are many species of breadfruit native to the Southwest Pacific Islands. They are closely allied to our mulberry and osage orange and all have a milky sap. The fruits of some species are excellent boiled or baked, and the seeds

of all are edible when cooked. Some species are seedless. The pulp of some can be eaten raw. The fruiting season of the different species varies, supplying a year-round supply of the fruit. The common breadfruit tree is moderate in size with dark, green-lobed leaves, and bears a roundish, rough-surfaced green or brownish fruit. It forms one of the most important food staples in the South Pacific Islands. The milky juice of the tree can be used as glue for caulking canoes or prepared as bird lime.

### Screw Pines

The screw pines are confined to the eastern hemisphere, and a large number of them are limited to the islands of the Indian Archipelago. They are found principally in close proximity to the sea, sometimes covering large areas with an almost impenetrable mass of vegetation. Most of them are large bushes with long, narrow, leathery leaves, thick and often twisted stems, and many prop roots. The red fruits and the seeds are available the year round, and are edible either cooked or raw. The fruit itself consists of rounded grains or sections enclosed in a hard rind. The terminal leaf bud may also be eaten cooked or raw. (See Figures 216 and 244)

FIG. 245. Sapodilla (*Achras sapota*)

FIG. 246. Mango (*Mangifera*)

### Mango

Mangos are tropical Asiatic trees, cultivated or wild. The common mango is one of the most delicious of tropical fruits, and is commonly found cultivated in nearly all tropical countries. The fruits of the wild species are edible, but some have a strong turpentine flavor. The ripe fruits are generally yellow in color.

**Sapodilla**

The sapodilla is a medium sized evergreen tree bearing brown fruits within which are large smooth black seeds. It grows wild in central and tropical South America, and is found wild and cultivated in other parts of the tropics. The fruit should be eaten raw, not cooked. (See Figure 245.)

FIG. 247. Baobab Tree and Fruit (*Adamsonia*)

FIG. 248. Cashew (*Anacardium occidentale*)

FIG. 249. Papaya (*Carica papaya*)

**Baobab**

The baobab tree occurs in Africa, Madagascar and Australia. It is easily recognized by its stout, bottle-shaped trunk which is sometimes 30 feet in diameter. The fruit is large, oblong or globular, four to eight inches long, with a woody shell enclosing numerous seeds embedded in a soft bready substance. The seeds are nutritious, the flesh tart, and the white gum which exudes from the tree makes an agreeable drink when diluted with hot water. Fibers of the wood can be used to make rope or twine.

### *Papaya*

The papaya is native to tropical America, but it is found cultivated and wild in all tropical countries. It is a straight, green or brown stemmed plant six to twenty feet high with large, melon-like fruits. The tree has a milky sap. The fruits of the wild plants are small. They can be eaten raw, and unripened fruits may be boiled as a vegetable. The milky sap contains the enzyme papain which will tenderize meat if put on it before cooking. (See Figure 249.)

### *Cashew*

The cashew is a spreading, moderate-sized evergreen tree found semiwild in fields and on the sides of dry bushy hills in tropical regions of Central and South America and is cultivated throughout the tropics. A grayish, kidney-shaped nut hangs from the red and yellow fruit. The fruit can be eaten raw, but the nut is poisonous unless roasted until all the oil is removed. (Figure 248.)

## SUBSISTENCE IN THE FAR NORTH

As you travel north or south from the equator, disease-transmitting insects, parasites, diseases, poisonous snakes, plants and animals decrease; physical hazards such as snow and cold increase. Trees become scattered and stunted, finally giving way to tundra, grasses and seas of ice. Food in the form of plant and animal life grows less abundant while the body requires more nourishment. Living off the land becomes increasingly difficult, but is possible with a gun, fire, equipment and suitable clothing. The arctic explorer, Stefansson, lived on the meat of land animals killed during every month of the year as far north as 80° latitude.

In general the plants and animals of the arctic zone and of the subarctic forests are circumpolar in distribution, so living off the land will be basically the same throughout these global areas. In other words the plant and animal food you can expect to find will be much the same in Alaska, Northern Canada, Labrador, Greenland, Northern Europe, Iceland, and Siberia. (See Map.)

Although plant and animal food is present in the arctic, it is not always easily available. Vegetation is scattered, but is most plentiful along the banks of lakes and rivers. Game may be abundant over a large area yet scarce in local areas at specific times.

FIG. 250. Lemming

## ANIMAL FOOD

You can live on meat alone if you eat both lean and fat. You cannot remain healthy on a diet of lean meat only.

Within the arctic circle are such animals as musk ox, wolves, polar bears, foxes, muskrats, lemmings and seals; and such birds as ptarmigan, gulls, owls,

FIG. 251. Crash Landing in the Far North (Army Air Force)

FIG. 252. Improvised Shelter Beneath Plane Wing (Army Air Force)

hawks, geese, brant, swans, dovekies, crane, loon, ducks, snow bunting and pipits.

Many of these animals migrate south during the long arctic winter, others do not such as caribou and musk ox. Some ptarmigan remain north of the circle

FIG. 253. Ptarmigan—Look Sharply for Them, as They Change Plumage to Blend with the Summer Grass and Winter Snow

and can be approached and shot, clubbed, or snared. Hare are found in the same local regions the year round and can be snared along their runs. Lemming can also be trapped or clubbed along their runways. You may have to dig down in the snow for them.

Farther south where trees occur, a greater diversity of birds, mammals and plants are found. Many of the deer family are in this area. The porcupine is

often encountered, and can be easily clubbed on the ground or shaken from a tree. Porcupines feed on bark. Limbs stripped bare are good signs of their presence. To avoid their sharp needles, pick them up by the loose skin under the chin.

In summer, birds and bird eggs will abound in certain areas. Gulls, terns, murres and dovekies nest in colonies along the coast, while ducks and geese can be found in the vegetation along the streams and lakes.

FIG. 254. Ruffed Grouse—Grouse Can Be Shot, Snared or Clubbed in Timbered Areas.

Seals are the staff of life in the Arctic, but it requires exceptional skill and knowledge to spear them. Even with a gun they are not easily obtained. Other large aquatic mammals such as whales and walrus are even more difficult to get.

Areas devoid of life occur in the Arctic as elsewhere, seals especially being concentrated in favorable areas and absent in many parts of the polar ocean. Even in those places where they are found in numbers they cannot always be hunted successfully. In winter they are hunted where there is an even layer of ice over water of fair depth. They can be expected in numbers where the ice is broken by current holes and tidewater cracks. Where the ice is thick and unbroken they will be scarce. Seals snort at their water holes and remain for some time taking air. Sneak up to the hole while the seal is taking a breath or dozing. Flatten out on the ice and remain still when it looks around. Move slowly and silently. They can hear slight sounds, even through the ice. Construct a white shield of parachute silk (as illustrated in Figure 255) and using this as a blind, slip up on the seal. When you get ready to shoot, try for a brain shot; otherwise, he may escape into his hole.

The walrus comes up to breathe, but does not scratch breathing holes and is thus harder to locate. It is probably the most dangerous animal of the arctic region.

The polar bear is found in practically all arctic coastal regions, seldom far from sea ice.

The caribou and reindeer are the most abundant of arctic land mammals. Their presence can be located by tracks, but careful stalking is necessary for a shot.

All of the large animals may supply food, implements, fuel and clothing. When hunting these animals with a gun, remember they are wary, and stalking them will take all your skill and patience. (See page 101.)

FIG. 255. Stalking Seal

Fish are plentiful in small northern streams. Salmon can be found from early spring to fall in coastal streams and rivers from Oregon through Alaska and from the New England states northward. When they are traveling upstream to spawn, they can be picked up by hand or clubbed. Salmon die after spawning in the headwaters. Their flesh deteriorates the farther they get from salt water. The flesh of these live but dying salmon may be poisonous. Watch for white salmon and let the pink ones pass. Trout can be caught in the larger lakes by fishing through the ice.

#### PLANT FOOD

When animal life fails and even such food as mice, fish and grubs are not available, you can still find plant food that will stave off starvation. In summer there is no great problem finding plant food and even in winter berries and roots are available beneath the snow, if you know where to look for them.

*In arctic and subarctic regions you may safely seek and try plant foods with the assumption that none of them are likely to be poisonous. The water*

hemlock is in most cases the only seriously poisonous plant but buttercups should also be avoided. The Amanitas (mushrooms) are present, but in many cases not even these are poisonous or at least deadly poisonous in far northern regions. It is important that you be able to recognize the relatively few nutritious plants from the far greater number that have no food value.

### **Berries**

*The salmon-berry* is the most important of the northern berries. It is circumpolar in distribution and always grows in a peaty soil. Its fruit is yellow and looks like a raspberry. The plant grows close to the ground, often covering many acres. These berries are available in summer and may be found frozen on the stalks in the winter and early spring. They can be eaten raw but are better cooked.

*The crowberry* is a small evergreen heathlike plant. The berries are brownish black, single seeded, juicy and sweet. They often can be found on the bushes in winter. They are circumpolar in distribution.

*Currants, cranberries, strawberries, raspberries and blueberries* are found where conditions are favorable for vegetative growth such as timbered regions, bogs, hillsides, and along streams. Remember the spots where you have found them, and look in the same types of places again.

### **Roots and Greens**

*Snakeweed* is a low plant with white or pink flowers in dense solitary spikes and is common on dry tundra. The rootstock is edible raw although slightly astringent, but is starchy and potato-like when roasted. It is circumpolar in distribution. (Figure 262.)

*Wild rhubarb or alpine knotweed* is a plant three to six feet high with small flowers. It grows on moist open or alluvial soil along river banks. The leaves and red stems are edible when cooked. After it becomes frosted it may be poisonous. It is circumpolar in distribution. (Figure 261.)

*Wooly lousewort* is a low plant with wooly spikes of rose-colored flowers. It is found on dry tundra regions of North America. The yellow root is sweet like carrots and may be eaten raw or cooked. (Figure 263.)

*Licorice-root* is a legume with pink flowers. It is found throughout the north as far as the Arctic Ocean. Its long tap roots taste like licorice when raw and carrots when cooked. In summer the root becomes tough and woody. (Figure 260.)

### **Bark and Buds**

*The bark and buds of certain northern trees that are eaten by animals can also be eaten by man.* The bark and buds of aspen can be eaten raw or cooked

FIG. 256. Crowberry (*Empetrum nigrum*)

FIG. 257. Salmon-berry (*Rubus chamaemorus*)

FIG. 258. Cranberry (*Vaccinium macrocarpon*)

FIG. 259. Mountain cranberry (*Vaccinium vitis-idaea*)

FIG. 260. Licorice-Root (*Hedysarum boreale*)

FIG. 261. Alpine Knotweed (*Polygonum alpinum*)

FIG. 262. Snake-weed (*Polygonum bistorta*)

FIG. 263. Wooly Lousewort (*Pedicularis lanata*)

but should preferably be boiled to a gelatinous mass. The buds of basswood, poplar, maple, the shoots of spruce, tamarack and the inner bark of willow, alder, hemlock, basswood and birch are all edible. The leaves of mountain sorrel, young willows and fireweed can be eaten when boiled.

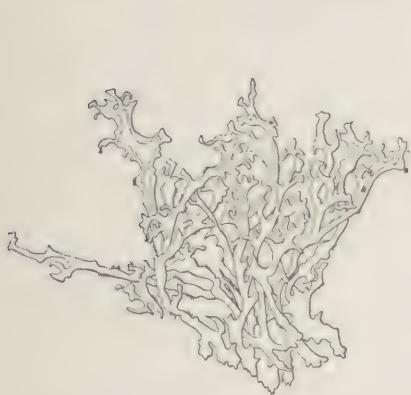

FIG. 264. Iceland Moss (*Cetraria islandica*)

FIG. 265. Reindeer Moss (*Cladonia rangiferina*)

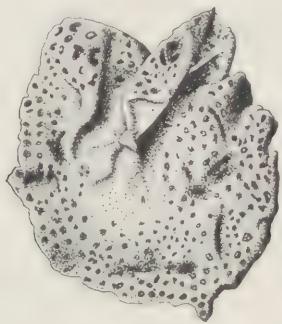

FIG. 265a. Rock Tripe (*Umbilicaria*)

### Lichens

The most widespread and surest source of emergency food in the far north are the lichens, some of which are mosslike in appearance. Often these small plants cover large areas, growing on rocks, trees, logs and in sand and gravel. They sometimes grow where there appears to be no soil. The lichens are gray, brown, or black in color and are rich in carbohydrates, furnishing food for many northern mammals. Some are eaten by Eskimos and European peasants during famine periods. None are poisonous, but some contain a bitter acid that causes internal irritation unless they are cooked in water, dried until brittle, and then powdered and boiled.

Among the most useful edible species are the following:

*Iceland moss* grows best on sandy soil and resembles a brown seaweed. It should be boiled for an hour or longer. (See Figure 264.)

*Reindeer moss* is gray-green in color and has a small globular "fruit" in a cup-like receptacle. It should be washed to remove grit and then boiled or roasted. It grows on the ground over extensive areas and is the most abundant of the food lichens. (See Figure 265.)

*Rock tripe or famine food* are flat leathery crinkle-edged lichens that grow on acid rocks throughout the north. They are smoky colored and brittle when dry, but dark-green on the upper surface when wet. The taste is bitter but not unpleasant. Rock tripe should be dried before being boiled, or it will cause diarrhea. When properly prepared it is nutritious and easily assimilated.

Plant life above tree line in the high mountains of the temperate and even tropic zones is similar in many respects to that in the far north and the Arctic. If it is necessary to live off the land in such regions, proceed as if you were in the far north.

## CHAPTER IX

# Environmental Hazards

Physical and biological hazards take a heavy toll of stranded men even when food and water are available. The ability to evaluate these and a knowledge of how to surmount them will give you confidence, diminish your hardships, and lengthen your survival time.

### PHYSICAL HAZARDS

In this chapter a number of these environmental hazards are discussed, together with ways of avoiding injury or illness from them.

#### *Effects of Sunlight and Heat*

*Sunburn* prevention is much easier than treatment. Many people are severely burned because they fail to realize that the effects of sunburn are not felt until

FIG. 266.—Be Prepared in Dress and Equipment for the Type of Country Over Which You Must Fly.

several hours after the exposure. If you wait until your skin turns pink or feels hot before you cover it, it will already be too late. Hazy and overcast days are sometimes the worst because there is much reflected light and little warning of sunburn. Danger of severe sunburn is greatest on a mountain snowfield, on open water, desert sands and beaches.

A "sunburn powder" of lime can be made by burning sea shells or coral in an open fire, and then crushing them. Mix the powder with water or oil and apply it as a paste over your face and body—for protection, not as a cure. Coconut oil (made by exposing coconut meat to the sun) is a good sunburn preventive. The best preventive is to keep covered as much as possible, with clothing or a makeshift covering.

For sunburn treatment, use the burn ointment and dressing in your first-aid kit. Tannic acid is effective in treatment of severe sunburn. Gather the *dark brown* bark from a tree, boil it, and then apply the solution to the burn. Inner bark of oak, hemlock, or chestnut wood and all parts of the mangrove tree are particularly rich in tannic acid. Boil betel nuts. They contain a high percentage of tannin.

### ***Heat Stroke (Sunstroke) and Heat Exhaustion***

*Loss of salt is a main cause of heat stroke, heat exhaustion and other less acute effects of heat.* Muscle stiffness after exercise will be reduced if you get plenty of salt. You sweat freely in the tropics and can easily lose salt beyond the danger point unless you replace it by taking extra salt on your food, and in or with your drinking water. If salt is not available, several swallows of ocean water a day will help replace the salt lost by sweating, will not be harmful if you are getting plenty of other water, and will relieve a sluggish, tired feeling.

In cold climates loss of salt is reduced, but you may be fooled in a hot, dry climate, at high altitudes, or in warm, windy areas where salt is lost through sweating but the sweating is not apparent because of rapid evaporation. When your body requires salt, even a strong solution will not taste salty.

Ascorbic acid also is lost through sweating. Replace it by eating citrus fruits.

In the tropics don't travel in direct sunlight without head protection. A head covering of leaves or cloth will be better than nothing. Don't overexert during the hottest hours of the day, especially if you are in poor condition. If the humidity is not too high, you can cool off when exerting in the heat by soaking your clothes. The resulting evaporation will keep you comfortable.

*Sunstroke* is the result of direct exposure to the sun. It may affect you suddenly, but is usually preceded by dizziness, nausea and headache. Your face will be flushed, your skin hot and dry, and your body temperature high. If the air is dry, you may not even feel unusually hot or uncomfortable preceding a sunstroke. The best preventive is to keep your head covered or wet, drink

plenty of water with salt, and cool your body by wetting it and your clothing. For treatment, lie in the shade with your head higher than the rest of your body; drink water with salt in it (a tablet to a glass of water), and bathe your head and body. *Heat exhaustion* is the result of long exposure to heat when the temperature and humidity are high. It may occur without exposure to the sun. The symptoms are different from a stroke. The skin is clammy and the temperature normal or below. Drink salt water, lie in the shade with head low, and cover up to keep warm.

### ***Snow Blindness***

Snow blindness is a painful inflammation of the inner side of the eyelids caused by constant exposure to the reflection of the sun's rays from snow. Its effect may range from slight inflammation to temporary blindness of several days' duration. The first sign of inflammation is a feeling of sand in the eyes. Preventive measures include travelling at night, use of a shade to protect the eyes from *below*, blackening of the eyelids, cheeks, and bridge of the nose, wearing a dark mask with small eye slits, or best of all, *dark glasses*. Cold water will relieve the pain. If temporary blindness has resulted, wear a dark bandage over the eyes.

Severe headaches are often indirectly due to excessive glare and exposure to sun. Eye inflammation often occurs among survivors at sea. It may be caused by exposure to wind, cold, water glare, salt water or a combination of these. Protect the eyes at the first sign of soreness.

### ***Acclimatization to the Tropics***

Men unaccustomed to tropical climates have less resistance to infection, and are also exposed to intestinal and gastric infections to an unusual degree. While you are adjusting to tropical conditions, "go easy" until you determine the kind and quantity of food, water intake, and amount of exercise you need for keeping physically fit.

When air temperatures are higher than body temperatures, the pulse rate, rate of breathing, and body temperature all tend to rise, for the heat loss does not keep up with heat production. A healthy man, well-acclimated to working under tropical conditions, may for hours run a body temperature of 103° or even 104° F., while exercising in the heat without marked ill effects. The individual acclimatizes to heat by sweating more freely. This must be accompanied by a greater water intake and an adequate amount of salt.

While diarrhea from infected food and water is always a danger in the tropics, constipation also should be guarded against. It may come from over-eating, over-exertion, lack of an adequate water supply, worry and interruption of regular habits. If safe liquids are available, drink them freely and eat

fruits. Coconut milk or several swallows of ocean water will act as a mild laxative. Don't use a laxative when nausea or abdominal pains are experienced since a ruptured appendix may be the result.

FIG. 267. Salt Water Sores

#### *Exposure to Water*

Long exposure to salt water (as when adrift in a boat or a raft) may result in sores and swelling. Fats or greases will help prevent salt water sores.

*Immersion foot* is caused by continued immersion of the feet in cold or ice water ( $60^{\circ}$  F. down) or by continued hiking in wet cold footgear. Pain is followed by swelling and numbness, and blisters and sores may result. The best preventive is to keep your feet as dry as possible (dry out socks and shoes) and to exercise your feet regularly. Don't wear tight boots or socks that bind the legs. In treatment, *don't rub or apply direct heat* and avoid breaking the skin. Keep the legs above body level and apply cold compresses or packs, keeping a layer of dry material between the compress and the feet to avoid wetting them.

### ***Strenuous Exertion***

In any climate, severe headaches are common after strenuous, unaccustomed exertion. An aspirin will ease the condition, but the best relief is sleep or rest. If you are hungry, moderate eating of hot broth or sweets will help. Nibble at food more or less continually. If you are not hungry, don't force yourself to eat but wait until you are rested and your appetite returns. This may be as long as twelve hours. Try not to exert over a long period of time without eating.

### ***Effects of Cold***

*Regulating Heat Loss.* Survival in extremely low temperatures is a matter of balancing heat loss and bodily heat production. You can balance heat loss to some extent by food intake and exercise, but since there is a definite limit to the amount of food you can utilize and to your muscular activity, *your main reliance for keeping warm must be in the reduction and regulation of heat loss by wearing proper clothing.*

Clothing should consist of a number of light garments that can be taken off or put on as the need arises to regulate heating and chilling. None should be tight enough to reduce blood circulation.

Outer garments should be windproof, but not so airtight as to cause excessive heat production and sweating. Inner garments should act as insulators. They should be form-fitting, light, soft, and loose enough to permit escape of perspiration. Your shoes should be big enough to allow you to wear at least two pairs of heavy socks.

Clothing is the "switchboard" by which you can balance heat production with heat loss. If you are overdressed and the day calm and sunny, it may be necessary to strip to the waist to prevent overheating. When walking or exercising lightly, removal of the windproof outer garment is often sufficient to prevent sweating. *Control of sweating is essential, for wet clothing conducts heat from the body and increases your chance of freezing.*

When keeping warm is a problem, never expose any more of the body than is absolutely necessary, since enough heat can be lost from uncovered hands, face, head and poorly insulated feet to chill the entire body.

*Frostbite.*—Local freezing of face, feet and hands is an ever-present danger at low temperatures. *Don't rub frozen parts, or expose them to heat rapidly.* Rubbing will break the skin and lead to infection. Thaw frozen parts slowly. Frozen flesh is white and stiff, while milder frostbite is dark red. Wrinkle the face continually to determine whether any part is frozen. The ears are especially susceptible to frostbite. Press your warm hands against them. When fingers become cold or frost-bitten, warm them against the bare skin of the body. Place frozen toes against the warm flesh of a companion or cup your

hands around them. Dry grass, moss or feathers placed inside shoes or between socks provides insulation against frostbite. A cloth tied over the face below the eyes and allowed to hang loosely at the bottom will protect your face and allow your moist breath to escape. Frostbite is especially apt to occur when you are traveling into a wind. A 60-mile wind at 0° F. feels colder and does more damage than a 15-mile wind at -30° or a calm at -50° F. Body heat is blown away by wind. Wild animals seek shelter in a cold wind, and you should do the same.

Remember that:

- (1) Temperatures are often warmer below the snow than above it and any windbreak will help conserve body heat.
- (2) Generally, hollows and valleys will be colder than protected slopes and ridges.
- (3) Lowest temperatures occur during clear, still weather. Temperatures usually rise during a blizzard or snowstorm.
- (4) Plenty of rest and food are most important in the Arctic. Never travel until you are exhausted. Take frequent rests, and sleep when you feel like it. Unless you are exhausted, the cold will waken you before you freeze.
- (5) For temporary rest and protection, dig into the snow with your back to the wind and your arms pulled out of your sleeves and held against the body for warmth. Don't sit directly on the snow if you can place something under you.
- (6) If you get wet in extremely cold weather, make a fire immediately in the most sheltered spot available, and dry out. Without fire, keep moving until your body heat has warmed and dried your inner garments.
- (7) Breathe only through the nose. This will warm the air before it reaches your lungs and reduce the danger of frosting them.
- (8) When your whole body has been exposed to severe cold, exercise and rub your limbs to increase circulation, and get something warm inside you.

### BIOLOGICAL HAZARDS

The sources of the greatest dangers are not always the most apparent. Many of the small forms of life, particularly the arthropods, can cause more real discomfort and danger than even a scarcity of food or water.

They may be irritating in themselves, but *their greatest danger lies in the fact that through their bites they transmit various weakening and frequently fatal diseases.*

The general information which follows is designed to tell you what to expect from them, how to evaluate the danger and discomfort, and how to take precautionary measures against them.

Supplement this general knowledge at every opportunity by getting specific information from medical authorities about the presence, transmission and prevention of diseases apt to occur in your particular area of operations.

It is not necessary for you to know a great deal about the diseases themselves. They are caused by minute parasitic plants and animals that enter the body, multiply, and set up a series of disturbances. What you're primarily concerned with are the parasite carriers which are responsible for getting the disease-causing organisms into your body. If you can keep the carriers away, or avoid them, you escape the diseases.

### HAZARDS FROM THE SMALLER FORMS OF LIFE

Arthropods are small animals with jointed appendages or legs, and include the centipedes, spiders, insects, ticks and crustaceans.

*These smaller forms of animal life which act as carriers are like all other forms of life in that they require certain conditions of environment for their existence.* Some forms are widely distributed and others are localized, while the habits of many make it easy to avoid them. They may not be able to live in bright sunlight, or they may come out only during the day or only at night. They may not range far from their breeding areas, or may be limited in altitude or latitude by their inability to survive low temperatures. Lack of proper breeding places will limit their numbers.

Because of all these factors, you will have only a very limited number of these disease carriers to take precautions against at any one time or place.

A carrier which may be dangerous under certain circumstances or in a particular area may be perfectly harmless at another time, or in another area. Frequently the particular disease organisms which they carry and transmit to man by their bite must at some time in the course of their life pass through one or more other animals or hosts. When these hosts are specific, *nothing else will do.* In such cases, if the hosts or man are absent, the disease organism will not exist in that area and cannot be transmitted, no matter how many potential carriers are present.

Malaria is a good example of a disease requiring a specific carrier and a specific host—in this case, man.

Malaria is transmitted to man by some (not all) species of infected Anopheles mosquitoes, and not by any other kind of mosquito.

The disease itself is caused by a microscopic protozoan (Plasmodium) which is injected into the blood stream through the bite of an infected mosquito.

These protozoa enter red blood cells, absorb their contents, and grow and divide into numerous individuals which are discharged into the blood stream by rupturing of the cell wall, and in turn each attack a new red blood cell. (The patient has chills and fever during the period when the discharge is taking place.) After a number of days, some of these parasites develop into

male and female forms and remain in the blood cells. If at this time the infected man is bitten by the right variety of Anopheline mosquito, the male and female protozoa are taken into the stomach of the mosquito. They unite to produce offspring which escape into the body cavity of the mosquito, and in turn are injected into a man when the mosquito bites him. *This life cycle can't take place unless the protozoa can spend part of their time in the blood of man and part in the stomach of the right kind of mosquito.*

Therefore an area which is free of Anopheles mosquitoes, or one which may have such mosquitoes but which has not been inhabited by man for some time, will be free of malaria. A great many other disease organisms require specific hosts to complete their development. *It is important for you to know the areas in which all the requirements for a specific disease exist, and how to recognize and avoid the transmitting organisms in those areas.*

Mosquito bites are at the best unpleasant, and at the worst can lead to delirium and even death, if you are exposed to them in large numbers over a long period.

Mosquitoes are much more numerous in some areas of the arctic and temperate regions during late spring and early summer than they are at any time in the tropics, but tropical mosquitoes are much more dangerous because they transmit diseases, among them malaria, yellow fever, dengue fever and filariasis.

All mosquitoes require water for breeding purposes. While only a small amount is necessary, they naturally will be most numerous near large areas of surface water and will not be found in desert areas unless they are blown there by the wind.

In temperate regions, various methods of getting away from heavy swarms of mosquitoes may be used.

Any breezy spot will be relatively free of mosquitoes and other small flying insects, but take care not to sleep *downwind* from a swamp or other wet area. A raft anchored off a lake shore, or a platform built in a tree so situated as to catch the breeze, may enable you to get a night's rest. When the breeze is from the sea, the shore will be mosquito-free. For temporary relief in an emergency, get into water and rest with only your nose and eyes above the surface. If you can climb 25 to 30 feet up a tree, you usually will "lose" mosquitoes, which normally do not fly that high; but first sprint to get rid of a swarm which may otherwise follow you.

Since mosquitoes can readily bite through light cloth it may be necessary to pad the inside of your clothing with leaves and thin strips of bark. Keep your clothing loose, except at wrists and ankles. A mosquito head net is a most important piece of emergency equipment, since your face and neck are the most difficult portions of your body to protect, and the net will also do

duty against blackflies and other pests. Coconut palm cloth, handkerchief, leaves and other makeshifts will help if you don't have a head net. Dangle these at the side and back of your neck.

Effective mosquito repellents are very useful and may be effective for several hours. At your base or station they are available from the dispensary.

### ***Mosquitoes and Malaria***

You have already learned how certain mosquitoes transmit malaria to man. Malaria may exist in any tropical climate where men live and where it is

FIG. 268. *Aedes* Mosquito

FIG. 269. Top, *Culex* and Bottom, →  
*Anopheles* Mosquito

wet enough for mosquitoes to breed. It can also be contracted during the summer in many temperate regions, but is not found in the cool climates of the northern and southern hemispheres.

*Take every possible precaution against malaria, particularly when you are alone and on your own.* The greatest danger is in regions with a large native population which may be infected. In such an area, almost any Anopheles mosquito may be a carrier (in most regions a great majority even of the Anopheles mosquitoes are not infected).

The Anopheles mosquito is identifiable by the fact that it rests with its tail end pointing upward at an angle. Its wings tend to be spotted. It is only active in the early evening and at night, though it may be well to take precau-

tions in dark or shaded areas, particularly on cloudy days. Because of its night-feeding characteristics, it is highly advisable in malaria regions to get a camp made and mosquito netting arranged well before dark. Since most malaria victims contract the disease while sleeping, a head or tent net should always be used for protection. Use atabrine or quinine as directed by your medical advisers.

### ***Mosquitoes Transmit Yellow Fever and Dengue Fever***

The Aedes mosquito transmits yellow fever and is largely responsible for transmission of dengue fever. Unlike the malaria-carrying Anopheles, the Aedes will bite at any time of day or night. (See Figure 268.)

"Shots" will protect you against yellow fever, which is most common in the Caribbean, West Africa, and in parts of Central and South America.

Dengue fever is transmitted like yellow fever. It is weakening but seldom fatal. It is widespread in the tropics and subtropics.

The mosquitoes which transmit it seldom range more than a quarter-mile from the little pools of water where they breed (can, tree-holes and the like) but they are especially abundant near human habitations.

### ***Mosquitoes Transmit Filariasis***

Filariasis is a round-worm infection transmitted by mosquitoes in the tropics and subtropics. The mosquito deposits minute larvae worms which bore through the skin and reach the lymphatics. There the worms mature and deposit the eggs which pass into the blood stream. Occasionally, affected portions of the body develop abnormal swelling which may reach huge proportions. There is no effective treatment of the infection at present.

### ***Flies***

Flies vary greatly in size, breeding habits, and in the discomfort or danger they can cause men. Some are vicious biters and the larvae of others infest wounds or even unbroken skin. Many contaminate food.

Like mosquitoes, some flies are active only at night, others only by day, and still others roam both day and night. In general, protective measures used against mosquitoes will be effective against flies, though some fly pests, such as the sand fly and the no-see-ums or punkies, are so small that they will go through ordinary mosquito netting. Many such pests are limited in range to comparatively short distances from their breeding areas, and can be escaped by moving out of the vicinity.

*Black flies or buffalo gnats* may cause you discomfort or danger, may transmit filarial worms and are found throughout the world in wet forested areas, particularly in the vicinity of running water. Various biting deer flies and

horse flies are abroad only in the day and may be numerous in regions where there are hoofed animals. They are stout-bodied and usually brightly colored. No-see-ums or punkies are tiny mottle-winged flies. They are found in fresh and salt wet areas throughout the world. They have an itching bite. Some species may carry filarial worms. If these gnats are abundant, move on; they are often local in distribution and are seldom encountered more than a half mile from their breeding areas. (See Figure 271.)

*Sand flies* are tiny moth-like flies which bite at night. They breed in humid places out of the sun and wind, such as crevices in trees and rocks. They can pass through ordinary netting, and are disease transmitters in such widely separated areas as Colombia and the Peruvian Andes, the Mediterranean, India, Ceylon, and China. They transmit verruga, pappataci and kala-azar fever. These flies seldom fly more than ten feet above the ground and dislike air currents. Sleep off the ground or in a breeze. (See Figure 270.)

*Tsetse flies* are found only in central and south tropical Africa. While some species transmit a sleeping sickness which may be fatal, the proportion of those infected is very small and so is the chance of contracting the disease. All require shade, usually bite only during the daytime, and prefer dark-skinned natives to whites. Avoid the forested and brushy borders of bodies of water in areas of possible tsetse fly infection. (See Figure 272.)

*Screwworm flies* are found in the Americas, especially the tropics, and are most likely to be abundant in the vicinity of unburied corpses and animal carcasses. They are active during the day and often deposit their eggs in wounds where the larvae feed on the living tissue. Danger is greatest when sleeping in the open as the flies deposit their eggs in the nostrils, particularly if these passages are irritated by colds or wounds. The larvae burrow into the nasal tissues causing severe pain and swelling. Stupefy the maggots with chloroform, then remove them with forceps. Where these flies are numerous, don't sleep during the day in the open without covering your face or using a net. (See Figure 273.)

*Blowflies* with somewhat similar habits may be encountered in parts of Africa, India, Australia and the East Indies.

*Bot fly* larvae bore into the skin producing painful swellings and boil-like lesions. Apply tobacco to the open boil to kill the larvae and squeeze them out without breaking them. (See Figure 274.)

### **Fleas**

Fleas are small wingless insects that move about by jumping and live on warm-blooded animals. (See Figure 276.)

In some areas their bites may transmit extremely dangerous diseases such as plague and endemic typhus. Fleas that live on rodents, particularly rats, can

FIG. 270. Sand Fly

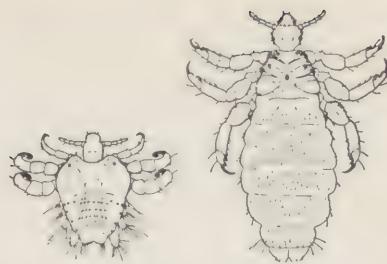

FIG. 275. Lice

FIG. 276. Flea

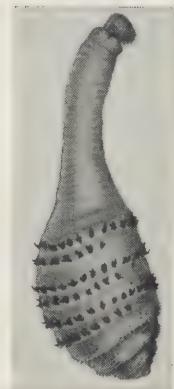

FIG. 277. Human  
Bot Larva

FIG. 278. Bedbug

FIG. 279. Hard Tick

transmit plague to man after feeding on plague-ridden rodents. Plague, a fatal bacterial disease, is apt to be contracted only in regions where epidemics are flourishing. It persists among wild rodent populations in various parts of the world, and occasionally breaks out in epidemic proportions.

If you must make use of rodents as food in plague-suspect areas, hang up the animals as soon as they are killed and do not handle them until they get cold. Fleas will soon leave dead animals.

The *tiny chigoe, jigger or sand flea* occurs in immense numbers in tropical and subtropical countries, particularly in dust near human habitations. The females burrow into the skin usually on the legs, feet and under the toe nails where they produced painful sores. The flea appears as a black speck under the skin and may be dug out with a sterilized needle or knife.

Precautions against fleas include use of derris or louse powder, and (in areas of sand flea infestation) wearing tight-fitting leggings or boots.

### **Lice**

Lice or cooties are wingless insects that live and feed on birds and mammals. Head, body and pubic lice infest men living under unsanitary, crowded conditions. You need not worry about becoming infested with them in the wilds. Their greatest danger lies in transmission of such diseases as typhus, trench-fever, and relapsing fever.

Both the lice and their eggs, which may be deposited on hair or clothing, must be killed. Control measures include use of general-issue louse powder, exposure of clothing to direct sunlight for a few hours, washing frequently in hot, soapy water, or leaving clothing near an ant hill, since certain types of ants feed freely on lice and their eggs. (See Figure 275.)

### **Bedbugs**

Bedbugs are brown wingless bugs with flattened bodies, which are found throughout the world but are most abundant in temperate regions. They feed at night, on human blood when available, and have a characteristic, disagreeable odor. They will leave bedding spread in bright sunlight. (Figure 278.)

### **Ticks**

Ticks are distributed over much of the world and are especially numerous in the tropics and subtropics.

The hard or wood ticks are found chiefly in wooded or brushy areas; the soft or leathery ticks in caves, around rocky ledges, and in the nests and burrows of animals. Both types may transmit disease, but fortunately *the percentage of ticks which are infected is in most areas extremely small.*

*Hard ticks*, which may cause secondary infection or transmit Rocky Mountain spotted fever or tularemia, are reasonably easy to guard against. In tem-

perate regions they are numerous only in late spring and summer, and are found in the woods away from direct sunlight. They are most common along a path or trail. Since it takes several hours for most hard ticks to bite, a thorough check of your body and clothing two or three times a day will eliminate danger of disease infection. (See Figure 279.)

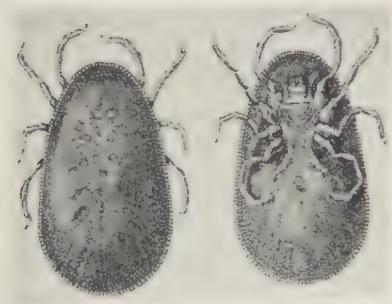

FIG. 280. Soft Ticks

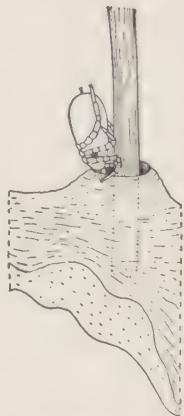

FIG. 281. Chigger (Nearly Invisible to Naked Eye)

*Soft ticks* bite quickly and fill with blood in 10 to 60 minutes. They may transmit relapsing fever, a weakening but usually not fatal disease.

In examining your body for ticks, look particularly at the base of the head, or hairy portions of the body under the arms, in the groin and where clothing is tight. Don't crush them on the body and be sure to get the head out or it may cause infection. A lighted cigarette or match held close to the tick's body will cause it to loosen its grip and it can then be removed entire. Kerosene or oil will have the same effect. In tick-infested areas avoid sitting on fallen logs and wear trousers tucked into boots.

Rocky Mountain spotted fever is found in many areas of the United States but particularly in the Rocky Mountain regions. It has a high mortality rate, but is comparatively rare. Closely related tick-borne diseases occur in the Mediterranean area, Brazil and elsewhere. Tularemia, a bacterial disease of rodents which can be contracted either from insect bites or through contact with infected animals, is present in the United States, Europe, Japan, and Russia, but is nowhere very common. Don't handle, prepare or eat rodents that were noticeably sick or very sluggish when killed.

#### ***Mites and Chiggers***

Mites and chiggers are tiny arthropods, some almost invisible to the human eye, which cause annoyance and irritation through their bites or through diseases transmitted by them. They include the human itch mite which causes

various skin diseases such as scabies, Norwegian itch, and barber's itch; and the harvest mites or chiggers, which cause irritating sores and may transmit Japanese river or Kedani fever in certain areas of the Far East, including South Pacific Islands. Human itch mites infest the skin and live beneath the scabby crusts made by their burrowing and feeding.

Washing in strong soap followed by application of sulphur ointments will help eliminate mites and chiggers after exposure to them. To protect against chiggers before exposure, dust fine sulphur or louse powder on your skin and inside your clothing, particularly around the ankles. Tucking trousers into boots also will help.

Human itch mites are particularly prevalent in areas where people live in crowded or unsanitary conditions.

### *Spiders*

Spiders in general are not particularly dangerous. Even the much-advertised tarantula is not known to bite with fatal or even serious effect. The black-widow or hour-glass spider of the southern half of the United States, together with tropical members of the same genus, should be avoided as their bites cause severe pain and swelling. All are of a dark color and marked with white, yellow, or red spots.

FIG. 282. Scorpion

FIG. 283. Black Widow Spider

### *Scorpions*

They are usually small ( $1\frac{1}{2}$  inches in length) but some are as long as eight inches. They sting with their tail spine but usually only when molested. Their stings are extremely painful, but seldom fatal. Since they hide in the daytime and are active at night, they may take refuge from light in shoes or clothing. In areas where they are found, shake out your clothing well and knock your shoes, bottom up, before putting them on.

### *Centipedes and Caterpillars*

Many-legged centipedes, found under logs, stones, or leaves, are numerous in the tropics. Their bites are poisonous but rarely serious.

Numerous hairy or spiny caterpillars will cause severe itching and inflammation if brushed against the skin.

### *Bees, Wasps, and Hornets*

They usually sting only in defense of themselves or their nests. The stings of an aroused swarm may be dangerous and even fatal. Varieties in the tropics range from small, stingless bees to large, militant varieties whose hives should be avoided even when in desperate need of food. In most cases, use of a smoke smudge to stupefy the bees, together with a head and hand covering, will permit you to take honey safely.

Some tropical ants sting severely and attack in numbers, but they can be easily avoided by moving.

Some people are much more susceptible than others to poisoning from stings. To susceptible individuals even a single sting may be serious. Applications of wet mud, ammonia, or soda will relieve the irritation. Juice from the leaves of climbing hemp weed, found near streams, swamps, and seashores, in parts of the Americas, Africa, and the South Pacific, is a good antidote for stings.

FIG. 284. Wasp

FIG. 285. Leech

### *Leeches*

Blood-sucking land leeches are common in very wet areas particularly during the rainy season in Borneo, Sumatra, India, Ceylon, the Philippines, the South Pacific Islands, Malay States, Australia, and in various parts of South America. They cling to blades of grass, leaves, and twigs and fasten themselves on any passing individual. Bites may cause intense discomfort, loss of blood, and may be followed by infection. Remove by touching with a lighted match, cigarette, or moist tobacco, and protect yourself by wearing trousers inside tightly laced boots. Leeches found in mud and shallow water

in other areas of the world are not apt to be numerous, and their bites are more irritating than painful, though they can cause severe trouble if swallowed in drinking water. (See Figure 285.)

### ***Flukes or Flatworms***

Blood flukes or flatworms, human parasites, are found in sluggish fresh water in Africa, parts of tropical America, Asia, Japan, Formosa, the Philippines and other Pacific Islands. There is little danger in areas remote from human habitation, or in salt water. The flukes pass through part of their life cycle in mollusks, usually snails, and the forms which emerge from the snails penetrate the skins of people who come in contact with them by drinking or bathing in infested water. They live in the blood vessels, feed on blood cells, and escape painfully through the bladder or the feces.

### ***Hookworm***

Hookworm is common in the tropics and subtropics. The larvae are usually acquired by going barefooted in areas where human excrement is found. There is no danger from hookworm in wilderness areas, away from human habitation.

### ***Fungus Infections***

Parasitic skin diseases (athlete's foot is one) are common in the tropics. They occur most frequently in the armpits, groin, and on the feet. The best protection against them is frequent washing and changing of clothing, particularly shoes and socks, and frequent bathing with plenty of soap. To treat an infection, wash with strong soap, soak the affected part in salt water, and use approved disinfectants as available. Such infections are incapacitating and are always difficult to cure.

## **POISONOUS SNAKES**

### ***Snake Sense***

Fear of snakes is out of all proportion to the facts. Common sense dictates a healthy respect for the poisonous varieties, but no more than to cause you to take normal precautions. Cases of bites by poisonous snakes are relatively rare.

Nowhere are poisonous snakes common or numerous over wide areas. Most of them are seclusive and timid, disappearing at the slightest disturbance. The majority of bites are by snakes which are suddenly surprised, stepped on, or grasped.

While the number of varieties of snakes is especially high in the tropics and decreases north and south of the equator, the danger in tropical jungles

is actually less than in rattlesnake- and moccasin-infested areas of the United States. If you know a few facts about their habits, and the general and specific areas in which they may be found, you can take normal precautions, give warning of your coming, and forget about fear of snakes.

General precautionary rules are:

1. Keep alert, particularly when climbing steep, rocky slopes.
2. Never tease or pick up a strange snake in a strange country.

This warning may seem unnecessary, but violation of it is the cause of many of the cases of snake-bite which do occur.

3. Knowing exactly what to do if you are bitten will give you confidence.
4. Protect vulnerable portions of your body, particularly the feet and legs. Even light clothing is an excellent protection against many varieties of poisonous snakes.
5. Many snakes roam at night. Therefore, cut down on night travel in snake country.
6. Learn the distribution and habits of poisonous snakes in general, and specifically of those in any area to which you may be assigned.

Snakes are cold-blooded meat eaters and live only in the temperate and tropic regions. Only 200 of the 2400 different kinds which exist are dangerous to man, and most of these will avoid you if given a chance. Only in Australia do the poisonous species outnumber the harmless ones.

Some areas of the world are entirely free of poisonous land snakes, including Madagascar, New Zealand, the Polynesian Islands, Cuba, Jamaica, Haiti, Puerto Rico, the Azores, the Canary and Cape Verde Islands, and Hawaii. While most sea snakes (distinguishable by their paddle-like tails) are poisonous, they do not attack man unless forcibly restrained, and they do not exist in the Atlantic area. Most poisonous snakes are confined to particular types of country and sets of conditions and are encountered only in such places. Certain of these local areas or habitats will harbor more poisonous species and greater numbers of them than others. In such places take every precaution and move out of the area if possible. Snakes feed on mice, lizards, birds, insects, frogs and other small animals and are generally found where such food is abundant.

Snakes cannot stand extremes of either heat or cold. In temperate regions they are active day and night during the warmer months, but hibernate or become inactive in cold weather. In desert and semi-desert regions snakes are most active during early morning and evening. During the heat of the day, they lie in the shade. Give warning of your presence when you seek shade, scan the ground before you stop to rest, and travel in the open as much as

possible. Many poisonous snakes are active only at night. When travelling in the dark, use a light, move slowly and avoid brushy areas.

Snakes with few exceptions travel slowly, though many can strike very rapidly. They cannot outrun a man, and only a few can leap entirely off the ground or strike as far as their own length. A sharp blow with a stick will break the vertebral column of average-sized snakes.

By now it should be clear that the danger of being bitten by a poisonous snake is extremely small, almost non-existent except in certain types of country and under certain sets of conditions.

There are no characteristics common to all poisonous snakes, and considerable training is necessary to be able to distinguish poisonous from harmless species. It is, however, comparatively easy to learn the common ones of a particular region.

### ***Colubridae***

This family, represented by such familiar snakes as our blacksnake and gartersnake, contains nearly two-thirds of the known species of snakes. None are poisonous except some of the rear-fanged snakes of Africa and southern Asia.

### ***Poisonous Long-Fanged Snakes***

The true vipers and the pit vipers are long-fanged venomous snakes. Most of them are thick-bodied with a distinctly flattened head. Many have keeled scales that give them a dull appearance as compared with the polished or satiny appearance of smooth-scaled snakes. (See Figures 286 and 287.)

The pit vipers include all the dangerous poisonous snakes of North America except the coral snake. They inhabit both the eastern and western hemispheres, but the most numerous and the largest species are in the New World. All have a deep pit between the eyes and nostril which is *not* easily seen, even at close range.

This family includes the various species of rattlesnakes, *all dangerous* and all confined to the New World, with the majority of species found in the United States and Mexico. The water moccasin is semi-aquatic, inhabiting sluggish waters of southern United States. The copperhead is common in eastern United States. Other pit vipers include the bushmaster of central and tropical South America; the fer-de-lance, a night prowler of southern Mexico and tropical South America; the arboreal palm vipers of Mexico, Central and South America (which frequently inhabit low trees or bushes and palm or banana trees) and the bamboo snakes of Asia.

True vipers are thick-bodied poisonous snakes found only in the Old World: in Europe, India, and particularly in Africa. Well known species

FIG. 286. Gaboon Viper (New York Zool. Society)

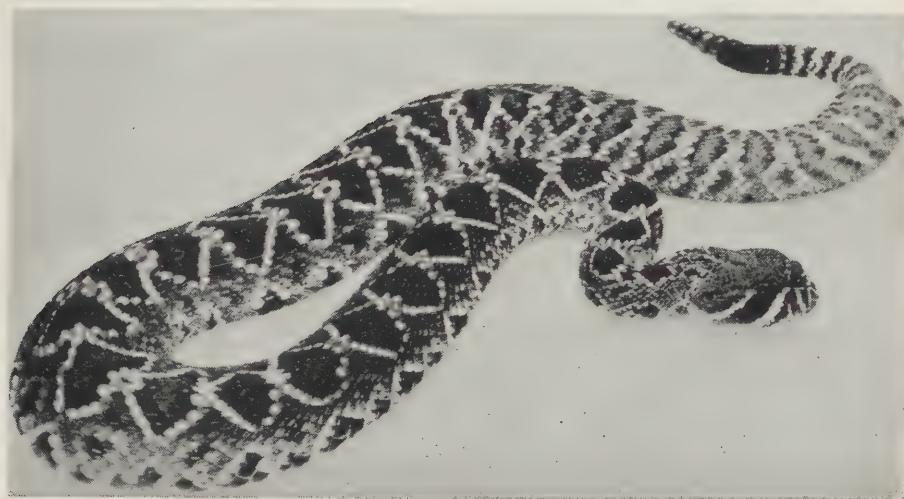

FIG. 287. Rattlesnake (Chicago Academy of Science)

include the Russell's viper of India, the cape viper of southern Africa, the puff adder of dry areas of Africa and Arabia, and the gaboon viper of tropical Africa. (See Figure 286.)

#### *Poisonous Short-Fanged Snakes*

The elapine snakes (including the cobras, kraits and American coral snakes) are among the most deadly of poisonous snakes, but even light clothing is a

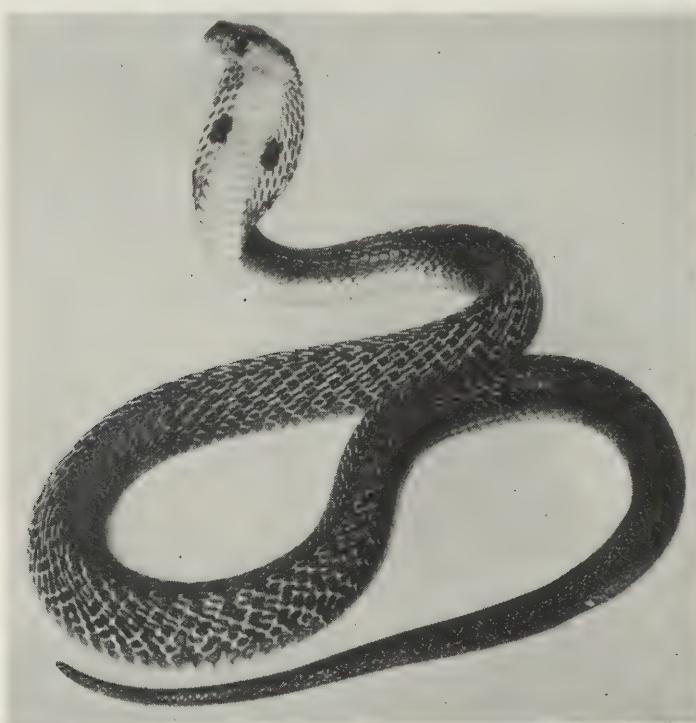

FIG. 288. Cobra (New York Zool. Society)

fairly good protection against them because of their short fangs. They comprise the majority of snakes in Australia, and many species are found in India, Malaya, Africa and New Guinea.

There are ten or more species of cobras, all confined to the Old World and all more or less able to spread the neck to form a "hood." The king cobra is the largest of all poisonous snakes. The Australian blacksnake, the tiger snake and death adder are among the most deadly and abundant Australian elapine snakes.

Coral snakes are small, brilliantly colored snakes confined to the New World. Many have a pattern of rich red, yellow and black bands and few are more than a yard long.

### *Sea Snakes*

Although sea snakes are poisonous, they do not disturb swimmers and are said not to bite unless forcibly restrained. Oriental fishermen are reputed to throw them from their nets with bare hands. Sea snakes usually are found close to shore or in tidal rivers, but they may be seen a hundred miles from the coast. They can be distinguished from river snakes by their flat vertically-compressed, paddle-like tails. Venomous sea snakes are not found in the Atlantic, but may

FIG. 289. Sea Snake

FIG. 290. Sea Snake

occur in large numbers off the shores of the Indian Ocean and the southern and western Pacific.

### *River Snakes*

These snakes frequent the rivers and bays of the East Indies, and are found from Bengal through Malaya to northern Australia. They are poisonous, but they must bite and hold in order to inject poison, and thus are not especially dangerous.

### *Boas and Pythons*

Boas and pythons are not poisonous, are slow moving and rarely attack man

unless molested. They are vicious and dangerous if disturbed because of their sharp teeth and power of constriction. The large species live only in dense jungle country, and are found in areas of Burma, Indo-China, the Malay Archipelago, the Philippines, southern India, China, South America, and central and southern Africa. Species such as the regal python and anaconda average between 17 and 22 feet in length.

FIG. 291. Mexican Beaded Lizard (Smithsonian Institution)

### **Lizards**

*Poisonous lizards are not found outside the western hemisphere. The only poisonous ones are the gila monster of the American Southwest and the beaded lizard of Mexico and Central America, both found only in desert areas.* The poisonous lizards are so sluggish, and their mechanism for injection of poison so poor, that cases of their causing injury to human beings are extremely rare. *No lizards, large or small, anywhere in the world, are poisonous except the two mentioned above.* Some lizards are excellent sources of food. (See page 90.)

### **Summary on Poisonous Reptiles**

From the previous discussion, you can see readily that because of their distribution, variations in habits and habitat, small numbers, and the nature of their venom-transfer mechanisms, only a few dangerous snakes are apt to be encountered at any given time or place, and that most of these are seclusive and timid, preferring to get away or remain undisturbed.

### **Snake Bites**

*Danger from snake bite is in proportion to the size of the snake, the type*

and quantity of venom injected, and the part of the body bitten. While venom may contain several toxins, the most important (the hemorrhagins and the neurotoxins) affect the blood and nervous systems, respectively.

Nausea and desire to void and defecate, thirst, severe headache, and bleeding from the wound, gums, and nose are frequent symptoms of snake bite.

Pain symptoms from the bite of the elapine snakes (cobra, krait, coral snakes) are comparatively mild, but the poison is absorbed rapidly and directly by the blood, spreads to all parts of the body, and acts quickly by paralyzing the nervous system and respiratory centers. Within the period of an hour a numb feeling grows progressively worse, resulting in partial paralysis of the affected area.

Venom of the viperine snakes will cause severe local pain followed by swelling that may continue for hours. It does most of its damage in the blood by liberating hemoglobin or producing internal hemorrhage or clotting. This venom is absorbed slowly through the lymphatic system.

Death dealing bacteria such as the gas-gangrene bacillus (*Bacillus welchii*) and *Streptococcus hemolyticus* occur normally in the mouths and venom sacs of snakes and cause secondary infections which greatly increase the seriousness of snake bite.

### ***First Aid in Snake Bite***

Quick and intelligent treatment is the most important factor in reducing the danger from snake bite.

1. Make a lengthwise cut through each fang puncture, as deep as the puncture, and make additional shallow cuts near the wound to drain the lymphatics. Cut parallel to blood vessels and tendons and *don't slash indiscriminately*. Prompt incision will reduce a lethal to a non-lethal dose.

2. Squeeze out the blood and venom, and suck it out if your mouth and lips are free from cuts. It won't hurt you unless it gets into the blood stream through a cut.

3. If a limb has been bitten, place a tourniquet *between the wound and the heart*, making it tight enough to cut off the return of the blood to the heart through the veins, but not to cut off flow to the wound, as bleeding will help remove the poison. You can do this by tightening up the tourniquet so that the pulse stops, then easing it so the pulse can barely be felt. If the wound is in the lower part of the arm or leg, put a tourniquet above the elbow or knee and another just above the wound and massage the limb toward the wound to encourage the blood flow. Loosen the tourniquet briefly every 20 minutes.

4. Keep quiet. Exercise increases the speed of spreading and absorption of the venom. Avoid all stimulants, including alcohol.

5. Cooling with a wet cloth or ice will retard the flow of lymph thus delaying the absorption of venom.
6. Kill the snake for identification. This is important if there is a chance of getting serum.
7. Don't cauterize (burn out) the wound or use potassium permanganate, as this destroys the tissues and does more harm than good.
8. Act rapidly but keep calm.

#### POISONOUS AND DANGEROUS AQUATIC ANIMALS

##### *Sharks*

The danger of being attacked by a shark or barracuda is greatly exaggerated in the minds of most people. Whether there is any hazard at all depends

FIG. 292. White Shark

FIG. 293. Barracuda

both on the locality and on the condition of the man in question. In general sharks are timid and wary creatures.

Sharks are curious, and will investigate any object in the water but are likely to attack only the dead, or the wounded and bleeding. Blood in the water attracts and excites them through their sense of smell. Any flow of blood should be stanchered as quickly as possible. Stay with your companions, as groups are less subject to attack than lone individuals.

Clothing, especially if it is dark colored, is a good protection, as light colored bodies appear to attract sharks. Be careful when cleaning fish at the edge of a raft and don't trail hands or feet in the water when sharks are present.

### ***Barracudas***

Barracudas are found in most tropical and subtropical seas, usually along coral reefs and near shoal waters. Danger from them is greater in murky water on reefs than in clear water. Under such conditions they apparently have difficulty recognizing their prey and thus are likely to attack objects in the water indiscriminately. They are seldom encountered in the open seas.

### ***Electric Ray***

The electric ray, or torpedo, is found both in open water and along sandy and muddy bottoms, both in tropical and temperate seas. It can give a paralyzing shock, but fortunately it is rarely encountered.

### ***Jelly Fish and Portuguese Men-of-War***

These marine animals have long stinging tentacles that produce painful stings and severe swelling which will last several hours. The greatest danger is not from the stings themselves, but from the fact that they may cause a swimmer to develop cramps, panic, and loss of energy which may result in drowning. Clothing should be worn as a protection while swimming in areas where these animals are present, and objects on the water surface resembling large bubbles should be avoided. If stung, make every effort to relax. When near a source of medical supplies, prompt application of ammonia will relieve the pain. (See Figure 295.)

*Whales, Dolphins and Porpoises* are large sea mammals, not dangerous to man.

*Cuttlefish, Squid and Octopus* have long, powerful tentacles, but those large enough to be dangerous live in the depths of the ocean and are rarely encountered.

### ***Stingrays***

Stingrays (stingarees) are flat fish with a powerful, venomous, tail stinger that can be driven through a man's foot leaving a wound likely to become infected. They frequent sand or mud bottoms, and in warm seas they may grow to several hundred pounds. You can avoid stepping on them by shoving your feet through the sand, or by poking ahead of you with a stick to frighten them out of your path. The sting of a large ray may be fatal. A small one can hospitalize a man. (See Figure 294.)

FIG. 294. Stingray

FIG. 295. Portuguese Man-of-War

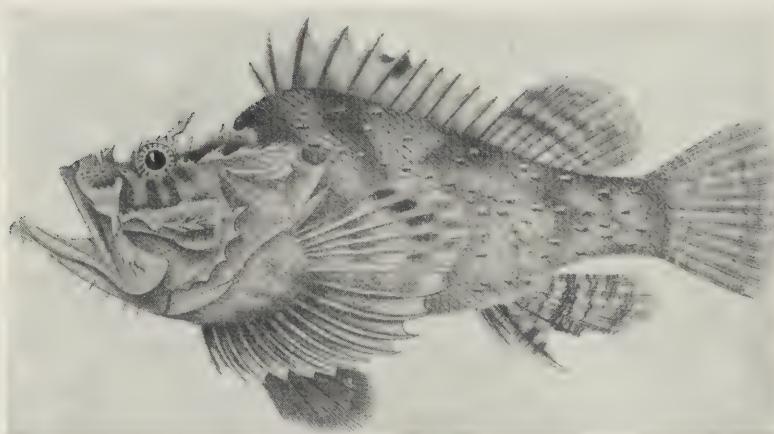

FIG. 296. Scorpion Fish

### *Scorpion, Stone, and Toad Fishes*

The stone and scorpion fishes of the Pacific Ocean and some of the toad fishes of tropical America are the most dangerous poisonous fishes. Their venomous spines may produce a sting which causes severe pain and swelling, followed by prostration. Treat a sting as you would snake bite. These fish are most apt to be encountered among coral head, where the unwary may accidentally step on them, or touch them with the hands while turning over coral rocks in search of food. The flesh of these fish is edible, but don't pick up these fish or take them off a hook with bare hands.

### *Sea Anemones and Sea Urchins*

Some of the sea anemones may produce an annoying sting. They are small, plant-like creatures which cling to rocks on reefs and in tidal pools. Some species of sea urchins found in the southwest Pacific have long, poisonous, needlelike spines.

FIG. 297. Sea Anemone

FIG. 298. Moray Eel

### *The Morays and Conger Eel*

These are snake-like fish inhabiting coral reefs. Normally they bite only when touched.

### *Shells*

The sharp shells of oysters and other mollusks, coral and starfish, cause wounds which heal slowly. You are almost sure to be cut if you try to wade or swim without shoes through a surf on coral shores.

### ***Crocodilians***

The crocodilians are confined to marshy lowlands, sloughs, rivers, and along the coast in the tropics and semitropics. All species are potentially dangerous, some more than others. A blow from the powerful tail of one which is surprised constitutes more of a real danger than the possibility of being bitten. The group includes the crocodiles, alligators, gavials and caimans.

All crocodilians prefer sluggish water and will rarely be encountered in swift water. Most of them are timid; if out on the banks, they will rush for water at the sight of a man. They will seldom attack unless you come on them suddenly or get between them and the water, blocking their natural path of escape. Either on land or in the water, keep a sharp lookout as they are difficult to see.

### ***Crocodiles***

The salt water and African crocodiles are the most dangerous of the species. The former is found in coastal swamps, inlets and tidal rivers of the South Pacific ocean. The latter, abundant in some areas of Africa and Madagascar, has a reputation as a man-eater. The American crocodile, found along coastal regions of Mexico, the West Indies, Central America, Colombia, and Venezuela, usually will avoid man.

### ***Gavials***

Largest of all the crocodiles is the Indian gavial, a timid creature confined to northern India, and living largely on fish. Natives swim in water where gavials are numerous.

### ***Alligators***

Alligators are found only in the southeastern portion of the United States, and along the Yangtze River in China. They are more active in the water and more vicious and treacherous than crocodiles.

### ***Caimans***

Caimans, resembling alligators, are found in the rivers of Central America and in tropical South America, east of the Andes.

### ***Fish***

*Only four fresh water fish are at all dangerous to man and all four are found in South America.* They are the caribe, the electric eel, the candiru, and the stingray.

The caribes (also known as piranhas or pirayas) are far the most feared of this group. They inhabit the Paraguay, Amazon and Orinoco river systems, are generally found in schools, and "go wild" if they encounter blood in the

water. They are about the size of a large sunfish, and have deep, blunt heads and powerful jaws armed with cutting teeth. They may attack any animal entering the water. People wading or swimming have been severely bitten and even killed by schools of these little fish. They live in smooth water, never in rapids. Clothing (including shoes) will protect against them.

The electric eel of the Orinoco and Amazon river systems delivers the most powerful shock of any fish. It is seldom encountered.

Fresh water stingrays are abundant in the muddy and sandy areas of South American streams, ranging thousands of miles up the river systems. Take the same precautions as against marine stingrays.

The candiru is a tiny fish found in the Amazon and Orinoco river systems, and apparently is attracted by water currents. Cases have been reported of this small fish swimming into the urethra of an individual urinating in the water. Small, hook-like, head spines prevent it from getting out again.

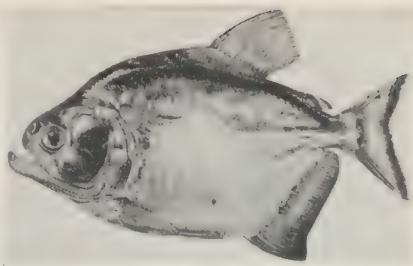

FIG. 299. Caribe

### HARMFUL MAMMALS

Generally, mammals large or small, flesh-eating or herbivorous are not of great danger to man. You may travel in jungles, grassland, desert or arctic regions without worry from this source. All wild mammals avoid man, and most of them are timid and wary. You will have more difficulty in locating lions, bears, and wolves than you will in avoiding them. You may consider yourself lucky if you get an opportunity even to see some of the supposedly dangerous carnivores. There are conditions under which mammals may be dangerous, but these are usually situations in which they are threatened or attacked by man.

#### *Circumstances under Which Mammals May Become Dangerous*

*When Wounded.*—Large animals such as elephants, bears, tigers, moose, wild boar and water buffalo will attack or charge when wounded, especially if cornered. If you find it necessary to shoot an animal which may be dangerous when wounded, use a large caliber gun if available; try to kill at the first shot.

*Protection of Young.*—Many mammals, which prefer to run away if given the opportunity, will fight when cornered, or if their young are harmed.

*Exiles and Man-eaters.*—Old exiles or hermits (such as elephants, boar, or buffalo) that have been cast off by a herd, are often cantankerous, and may

charge you if disturbed or irritated. They will be alone or straggling in the vicinity of a herd. Almost all man-eating lions, tigers or leopards are old beasts that no longer can successfully hunt wild animals and have resorted to killing man. Such animals are rare. Take reasonable precautions when sleeping if such an animal is known to be in the area. A hammock or platform in the trees will eliminate danger from tigers or lions, although leopards are excellent climbers. Tigers are found primarily in jungles of southeastern Asia, including India, Burma, and Malaya, Sumatra, Borneo, and Bali. Lions are confined to Africa and a very small region of western India and Persia. They are found in open regions of grass and scrubby trees. Both lions and tigers are shy and seldom seen, but may prove dangerous when suddenly disturbed or in a region where game is scarce.

*Stampeding.*—Mammals that live in herds can be dangerous if suddenly frightened into stampeding. Wild hogs or boars have been known to attack man.

### **Bites**

Bites from all canines (dogs, jackals, foxes) as well as some other meat-eaters may cause rabies. There is no need to worry unless this disease is known to be prevalent or the animal was particularly vicious or noticeably sick or paralyzed.

The Pasteur (vaccine) treatment for prevention of rabies is highly effective. The treatment may safely be delayed for several days after you have been bitten unless the bite is in the region of the head or neck. In any doubtful case consult a doctor as soon as possible.

Blood-sucking vampire bats, found only in South America, are not dangerous unless their bite becomes infected. Mosquito netting will keep them away, and should be used at night in areas where these bats are found.

## **POISONOUS PLANTS**

*As a general rule, poisonous plants are not a serious hazard, but under certain conditions they are dangerous.* Plants may be poisonous to eat, poisonous merely to touch, due to toxic juices or oils, and poisonous due to stinging hairs that come in contact with the skin.

The dangers from poisonous plants in other parts of the world is no greater than in any part of the United States where poison ivy, poison oak, and poison sumach occur.

### **Plants Poisonous to Eat**

There are numerous plants which are poisonous to eat in whole or in part. To attempt to learn these would only be confusing. Learn the plants that are

edible, and if it is necessary to try strange plants, eat only minute quantities and wait a while before trying more.

FIG. 300. Poison Ivy (*Rhus toxicodendron*) Grows as a Shrub or Creeping or Climbing Vine

### Plants Poisonous to Touch

This group will cause you most trouble. Contact with them may cause severe eruptions, swelling and inflammation. They are particularly dangerous in the vicinity of the eyes. Some people are immune or only slightly affected by contact poisons, while others are extremely susceptible. This is something you should learn about yourself. There is a greater danger of being affected when you are overheated and sweating. The plants themselves may vary in toxicity at different times of the year. Don't use the wood of any contact poisoning plants for firewood. Avoid contact with the milky juices of all unfamiliar trees and take particular precautions against getting such juices in your eyes. It will be helpful for you to learn the appearance and effects of the contact-poisoning plants found in the United States, and to use this background of experience to help you in other parts of the world. The method of

FIG. 301. Poison Oak (*Rhus diversiloba*)

FIG. 302. Poison Sumach (*Rhus vernix*)  
Grows Only in Wet Swampy Areas

FIG. 303. Liga (*Semecarpus*)

FIG. 304. Black Poison Wood  
(*Metopium*)

poisoning, the symptoms and to some extent the appearance of the plants, will be similar.

Most of these plants, both tropical and temperate, belong to two families—the sumach and the spurge.

#### ***Poisonous Contact Plants of the United States***

The three most important contact poisonous plants in the United States are poison ivy, poison oak, and poison sumach. Their toxic principle is a resinous alkaloid that occurs in all parts of the plant.

Symptoms may take from a few hours to several days to appear. They consists of reddening, itching and swelling of the affected parts, followed by the formation of blisters. The infection may be localized or spread over the body.

All of these plants have compound leaves and a small round grayish green or white fruit. They can easily be avoided by learning where they grow and what they look like. The best treatment after contact with these plants is to wash thoroughly with a strong soap. (See Figures 300-302.)

#### ***Poisonous Contact Plants in Other Parts of the World***

Most plants in other parts of the world that produce skin eruptions similar to poison ivy and poison sumach belong to the same family.

Some of these plants are:

1. The Rengas trees of India, Malaya and the South Pacific Islands. Their sap causes severe skin eruptions. Liga, a small shrub of this group found in the Philippine Islands can be identified by the black sap along the trunk. (Figure 303.) Many of these plants are large forest trees and there is little likelihood of trouble unless you climb or cut them.

2. Several species of *Mangifera* to which the edible mango belongs. They are found in tropical Asia.

3. Black poison wood of Central America and the West Indies. (Figure 304.)

4. Carrasco, common shrubs in the West Indies.

5. The Chinese lacquer tree of China and Japan.

Among the spurges the following should be avoided:

1. The beach apple or manzanillo of Central America and tropical South America, the West Indies and Mexico causes skin inflammation and may also cause blindness if the sap gets in the eyes. It is a small tree with smooth, pale-brown bark and "crabapple-like" fruits. It is found in thickets along the coast. Immediate bathing in sea water will counteract the effects of the sap. The fruits are poisonous to eat. (See Figure 305.)

2. The "blind eye," white mangrove found in Australia, the South Pacific Islands and India grows in mangrove swamps, salt marshes and along the

seashore. It is a shrub or small tree whose white sap causes severe skin irritation and may cause blindness.

3. The monkey pistol or sandbox tree of tropical America, Panama, and the West Indies is a large tree with spiny trunk whose sap is irritating and

FIG. 305 Beach Apple (*Hippomane mancinella*)

FIG. 306 White Mangrove (*Excoecaria*)

FIG. 307. Sandbox Tree (*Hura crepitans*)

FIG. 308. Sapium Jamaicense

may cause temporary blindness. The small pumpkin-like fruit is also poisonous.

4. The milky juice of a number of species of the genus *Sapium* found in the tropics of both hemispheres causes serious skin inflammations.

5. The castor oil plant belongs to this family and contains poisonous and purgative qualities. A remedy that many natives use for milky juices in the eyes is to wash the eyes immediately with warm milk.

The Upas or Ipoh tree is notorious for its poisonous properties. Natives of the South Seas and Indian Archipelago use the sap of this tree to poison their arrows, but there is no danger from contact with the tree itself.

Strychnine trees furnish curare, the poison which South American natives

FIG. 309. Stinging Nettle (*Urtica dioica*)

FIG. 310. *Jatropha urens* of Tropical America

apply to their spears and arrows. Treat poison arrow wounds as you would snake bites.

#### **Plants with Stinging Hairs**

Plants of this group contain fine hairs which produce a burning sensation when touched, followed by the appearance of small red welts. This sting, due to formic acid, is usually not dangerous. Contact with the stinging nettle found in waste lands of the United States and Europe will give you an idea of what to expect from tree nettles and this group of stinging plants in other parts of the world.

#### **IMAGINARY DANGERS**

To the man alone in strange surroundings, dangers which exist only in the imagination frequently are the chief source of worry unless he has trained himself in advance to know what the few real hazards are and to concentrate on surmounting them. Vast, desert wastes; endless snow or ice in the Arctic;

infinite expanses of ocean; rugged mountains, or dark confining jungles—all give rise to imaginary fears. Apparent silence, continuous wind, or unexplained noise will magnify the effect of strange surroundings.

If silence bothers you, tune your ear to pick up high-pitched insect voices. You may find that there are lots of small previously unheard noises. Cuss a little just to hear your own voice. If the loneliness is depressing, or starts you thinking on your insignificance in the vastness about you, remember such thoughts are normal in such a situation, and will help alleviate your fear of personal dangers.

Jungles are noisy day and night. Birds, such as parakeets, may flash through the treetops like a squadron of planes and be almost as noisy. Peacocks calling in the early morning or evening may sound like anything your imagination can conceive. Some birds will be noisy all night long. Mammals, such as cheetal or sambar, may bark at night. Tigers and leopards may roar or moan, and jackals howl. These and a thousand others are all natural sounds, and in some cases can be helpful. A prolonged quiet or unusual excitement indicates that something has disturbed the jungle life. Cheetal and sambar (deer) may bark nervously when tigers or leopards are near. Langurs and other monkeys give warning of the presence of large cats. Jays, crows, babblers and magpies scream excitedly at the approach of man or other enemies. Frogs usually stop croaking at the approach of man. Experience may enable you to utilize these noises in detecting the presence or approach of an enemy.

The eyes of numerous animals gleam at night in the presence of a light. Cats are among them, but the chances of seeing the eyes of a tiger, lion or leopard under such conditions are very slim. The eyes of spiders, land crabs, large insects and birds such as the goatsuckers also shine. Remember to rely on reason and knowledge. Don't let your imagination run riot.

#### DEALING WITH NATIVES

Native people throughout the world vary a great deal in their attitude toward strangers. At times it may be best to avoid them; but in most cases you can seek their aid with confidence. They will be friendly and will know the country well. The help and friendship they extend to you will be directly proportional to your own good will and good conduct toward them.

The following are a few general pointers to remember when dealing with native people:

- (1) Approach natives with a smile and confident bearing. Attempt to make your wants known to the man who by appearance and action seems to be the chief.
- (2) Never show fear, and don't threaten or order the natives around.
- (3) Treat them as equals, be eager to learn, and show enthusiasm and

admiration for their skill and proficiency in guiding and supplying you with the necessities of life. With a little subtle praise, they will outdo themselves in your behalf.

- (4) Observe the way the natives do things, then imitate them.
- (5) "Actions speak louder than words." If you can outdo natives in feats of strength or skill, you will be held in esteem for this above all else.
- (6) Try to learn and follow the customs and laws that govern the religious, social, and private lives of the natives. Be extremely cautious in your attitude toward native women.
- (7) Insofar as it is possible, eat only hot food that has been boiled or otherwise thoroughly cooked, and fruits that have not been peeled or husked. Avoid eating raw greens handled by the natives. Boil your own drinking water and all milk, or make sure it is done. Insist on this.
- (8) Sleep well-covered, and by all means use a mosquito netting if you have one,
- (9) Among natives your problem of food, water, and shelter will be solved, but the danger of disease is greatly increased. So take all possible health precautions without giving offense to your hosts.
- (10) Remember that not only your own fate but that of many other members of the Allied forces may depend on your treating native peoples well.

## APPENDIX

# The United States Naval Aviation Survival Training Program

# The United States Naval Aviation Survival Training Program

The United States Naval Aviation Survival Training Program has been designed to impart a wide range of knowledge and experience to large groups of men in a limited time. In a training program it is impossible for large numbers of men actually to live off the land, but it is possible to teach the fundamentals of how to do it and to show how these fundamental principles can be applied to any region of the world.

The program now operating in the U. S. Navy Pre-Flight Schools accomplishes this by means of:

1. The use of this manual as a basic text
2. Illustrated classroom lectures
3. Field trips planned to impart experience or to simulate emergency situations
4. Demonstration areas

## CLASSROOM LECTURES

The classroom lectures include Chapters I, III, IV, V, VIII, and IX. Information in Chapters II, VI and VII can be adequately covered on the field trips. Instructors should closely coordinate classroom instruction with the field work. Wherever possible the classroom lectures should be given by officers who instruct in the field. Reading assignments should be made before each lecture period, and the instructor should confine his discussion to emphasizing and clarifying the most important information and answering questions. Colored slides, colored movies and demonstrations have been prepared for each lecture to emphasize important information and technics and to add interest and inspiration.

The following plan is recommended but may not always be practical because of time. However, where the complete lecture and hiking plan is not possible at the Pre-Flight Schools every effort should be made to cover the omitted material at subsequent stages of training.

## LECTURE I

ASSIGNED READING: Chapter I—General Survival Hints

The instructor should emphasize:

1. The importance of being prepared for an emergency and thinking a situation through

2. Individual emergency equipment
3. How to search intelligently for food
4. The association of plants and animals and their distribution throughout the world
5. Careful study and explanation of World Map showing land areas where living off the land is essentially the same

## LECTURE II

### ASSIGNED READING: Chapter III—Water

The instructor should emphasize:

1. Importance of water and its use in an emergency
2. Methods of locating water
3. Principle of the water table
4. Plants as a source of water
5. Water-borne diseases

## LECTURE III

### ASSIGNED READING: Chapter IV—Wild Plant Food

The instructor should emphasize:

1. General information concerning plant food
2. The importance of plant habitats in locating plant food
3. The similarity of species of plants of the same group (Genus)
4. The value of knowing a few edible plants of the U.S. found elsewhere in the world
5. The importance of learning food plants of an area from natives or authorities before an emergency arises

## LECTURE IV

### ASSIGNED READING: Chapter V—Wild Animal Food

The instructor should emphasize:

1. That a great variety of wild, easily available foods are to be found in or near streams, lakes and rivers
2. That the small forms of life such as insects, clams and crustaceans are in general the most available source of animal food
3. Fishing methods and technics
4. Why all freshwater food should be thoroughly cooked
5. That birds and mammals have definite habits that can be utilized in their capture
6. Trapping and stalking principles

FIG. 311. Lay Out Cross Country Hikes so as to Encounter Natural Obstacles

## LECTURE V

**ASSIGNED READING:** Chapter VIII—Survival in Special Areas (Survival at Sea and Along the Seashore)

The instructor should emphasize:

1. How to conserve energy on a life raft
2. The danger of drinking sea water
3. Methods of getting fresh water at sea
4. The importance of knowing how to fish and how to improvise fishing tackle (Demonstrate)
5. That animal seashore food is quite similar in appearance and habitat throughout the world
6. That poisonous seashore foods are relatively few and rather easily identified

## LECTURE VI

**ASSIGNED READING:** Chapter VIII—Survival in Special Areas (The Far North and Tropical Plant Foods)

The instructor should emphasize:

1. That living off the land in the north is difficult but there are few serious diseases to worry about
2. Animal foods that will be found in the far north
3. That there are no seriously poisonous plants in the far north with the possible exception of the Amanita and water hemlock.
4. Importance of eating fat in a cold climate
5. Palms as an excellent source of emergency foods
6. That many tropical plants must be specifically identified to be eaten with safety, and therefore the cadet should familiarize himself with some of the more common ones

## LECTURE VII

**ASSIGNED READING:** Chapter IX—Environmental Hazards

The instructor should emphasize:

1. Physical effects of heat—precautions
2. Physical effects of cold—precautions
3. The great danger of malaria in the tropics
4. Methods of avoiding insect-transmitted diseases
5. General information to dispel imaginary fears of poisonous snakes
6. What to do in case of snake bite
7. That some aquatic animals can be seriously dangerous, but as a rule such dangers can be rather easily avoided
8. That poisonous plants are not generally a serious hazard, and a general

knowledge of American species will be of help in recognizing such plants anywhere in the world

## 9. Instructions on how to deal and live with native people

### FIELD TRIPS

The purpose of the field trips is to impart the information, technics and experiences deemed necessary for surviving in wilderness areas.

It is not practical to follow a hard and fast syllabus in conducting survival hikes or field trips as the information and technics to be included in any one field period will vary with the season of the year, topography, vegetation, weather conditions, and such local factors as length of instruction period, and distance to suitable terrain.

This manual contains the basic information and technics that should be worked into the trips. Use it as a guide and reference in planning and executing field trips.

The success of these hikes and the value of them to the cadets will thus, to a large extent, depend upon how thoroughly they are conceived, arranged and organized by the officers conducting the Survival Program at each Pre-Flight School.

Several proposed field trips are included in this syllabus to serve as a guide. It is not expected that they can be rigidly followed and details of instruction and procedure have purposely been omitted. Neither have they been designed for a definite time period. Officers will have to experiment and fit into each field trip as much information and as many technics as possible.

Take advantage of all natural facilities at the station, such as streams, swamps, rough and wooded country or cliffs, in planning the field exercises.

Each field trip should be planned to include a maximum of physical exercise with specific instruction on some phase of survival. A definite subject such as orientation methods, shelter construction, fire-making, etc., should serve as a basis for each field trip and if the hike is properly planned and conducted, much additional information can be imparted en route. For example, edible plants and animals should be continuously pointed out on all field trips. Poison ivy, poison oak and poison sumac should be noted and their relationship to similar plants in the tropics made clear to the cadets. Every possible phase of survival should be integrated into each field trip so that previously imparted information and technics are repeated. In this way the cadets constantly learn new information and at the same time review things taught on earlier hikes.

Wherever and whenever possible the cadet should be allowed to learn by doing. In many cases demonstrations by the officer-in-charge will have to

suffice, but it is most important that the cadet be put *on his own*, as much and as often as possible.

#### GENERAL INSTRUCTIONS FOR FIELD TRIPS

1. At least three officers well qualified in woodcraft and survival technics should accompany a battalion on every hike.
2. Platoon officers should accompany their platoons on the field trips and act as instructors.
3. For demonstrations, the battalion should be broken down into platoons and the demonstrations be conducted by the platoon officers. The survival officers should check and assist the platoon officers in these demonstrations.
4. Whenever possible each cadet should be allowed to participate as an individual; so that he has actual experiences sighting a compass, building a fire, cooking a meal, etc. When this is not practical, use the smallest unit possible so that a maximum number of men participate.
5. Plan all field trips using topographic or aerial maps as a basis. (Pages 232-233.)
6. When issuing equipment, have it available so there is no delay, and make each cadet, as well as officers, responsible for its safe return.
7. Use K rations for all meals. Acquaint cadets with the use of D ration and pemmican.
8. Carry packs, canteens, knives, rations and first-aid kits on field trips.
9. Be prepared for all weather and carry through an outdoor exercise regardless of weather conditions.
10. Inform cadets as to type of clothing to be worn and extra clothing to be carried.
11. Advise cadets to read material in manual relating to field trip.
12. Caution cadets concerning property rights.
13. Caution cadets concerning any poisonous snakes, plants or other natural hazards in the area.
14. Explain the purpose of each field trip and any details of procedure.
15. Instruct and question cadets at every opportunity en route and during stops.

#### SUGGESTED FIELD TRIPS

##### HIKE I—ORIENTATION AND TRAVELING

###### *Purpose*

To instruct cadets in the use of a compass in densely wooded or jungle country, methods of orienting themselves, and technics of traveling in such country.

**Procedure**

1. Hike battalion to rough wooded area.
2. Explain how to hike in wooded country.
3. Supply each cadet with an aerial map and compass, and hike by platoons or smaller units across country on a given course to a definite objective. Follow compass readings regardless of obstacles.
4. Hike back to starting point using compass to circumvent swamps, ridges, river bends or other obstacles. Average compass readings to maintain course. Explain use of a baseline.
5. Point out and explain the use of landmarks, sun, and bushmarks in keeping a course. Emphasize the value of constant observation.
6. Demonstrate method of telling direction with a watch.
7. Suggestions for similar but more advanced hikes:
  - (a) If time and circumstances permit, a hike may be arranged for a small number of hold-over cadets.
  - (b) Drop cadets from a bus or truck in small groups. Supply them with a topographic map and compass. Locate their position on a map and instruct them to set a course for the base ten miles away. Select rough country for the hike. Instead of a direct course to the base, several bearings intersecting various landmarks on the map can be given. (See pages 232-233.)
8. A still more difficult test can be arranged by placing previously blindfolded cadets at an unfamiliar point with map and compass. Do not orient them, but instruct them to hike until they can recognize a landmark on the map, and then set a course for the station.

Reference—Chapter II.

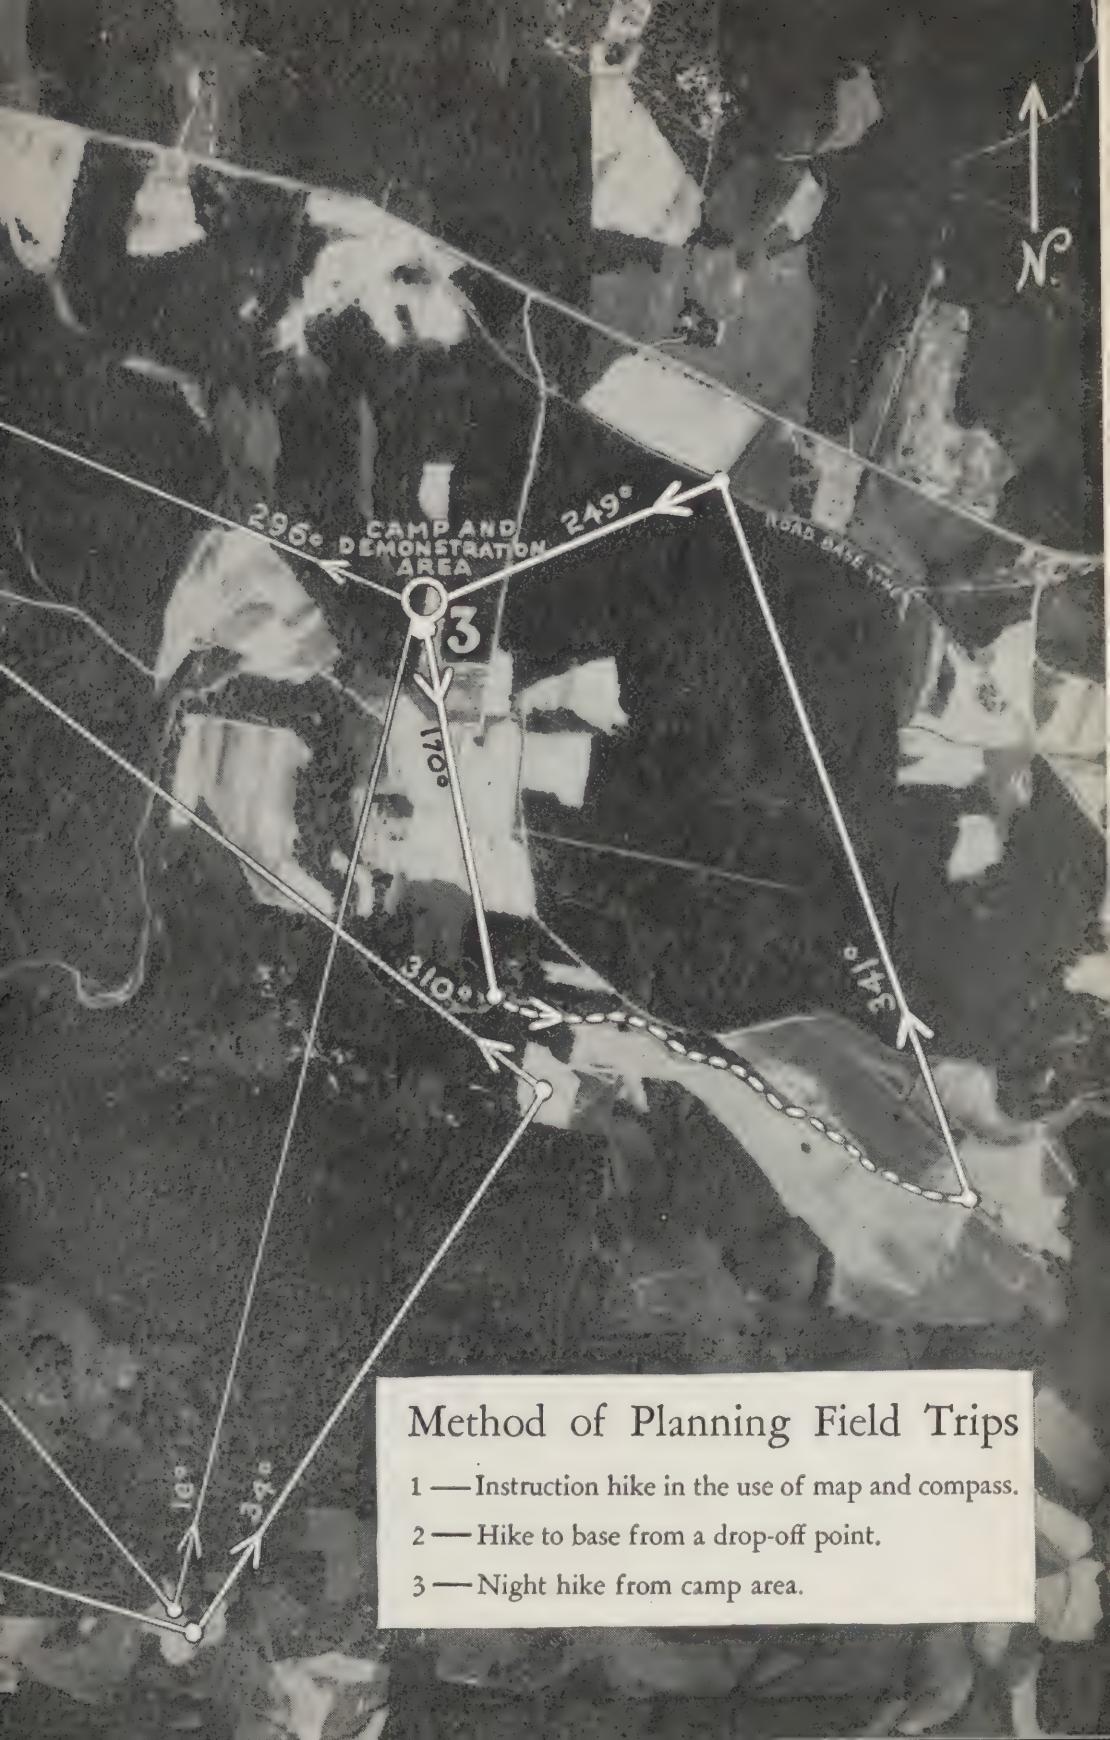

**HIKE II—WILD FOODS AND WATER****Purpose**

To acquaint cadets with the use of wild edible plants, to give them general instructions on how to look for plant and animal food, and to show techniques of finding and obtaining drinking water.

**Procedure**

1. Officers in charge of program should, in prior reconnaissance, locate areas where particular species of wild food plants are abundant. This will prevent loss of time and give a definite destination for the hike. One such selected area should be in the vicinity of a creek, river, lake or shore where edible water plants grow. When particular berries, fruits, or nuts are in season the hike should be planned to pass through regions where these wild foods are found.

## Method of Planning Field Trips

- 1 — Instruction hike in the use of map and compass.
- 2 — Hike to base from a drop-off point.
- 3 — Night hike from camp area.

2. Demonstrate methods of searching for food emphasizing observation, the value of habitat recognition, and plant and animal indicators.
  - (a) At least some widely distributed food plants found both in the vicinity and in other parts of the world should be pointed out. (See pages 61-74)
  - (b) Demonstrate with the proper plants that leaves, sap, stems, buds, roots and fruits are all potential food sources.
  - (c) Let the cadets taste and eat the wild foods, but don't encourage this if demonstration plants are scarce.
3. Show cadets where to look for mussels, crayfish, salamanders, frogs, water snakes and insect grubs.
4. Instruct cadets in methods of obtaining water. One or more of the following can usually be demonstrated.
  - (a) How to tell whether water from streams is relatively safe to drink.
  - (b) Water from grape and other vines.
  - (c) Water from desert plants.
  - (d) Water along the seashore and low river flood plains (digging).
  - (e) Water reservoirs—plants.
  - (f) Demonstrate how the presence of certain plants and animals indicates the nearness of water.
5. Include information on boiling, filtering and deodorizing water when practical to do so.
6. Additional compass and orientation practice can easily be worked into such a hike.

References—Chapters III, IV and V.

#### HIKE III—SHELTER

##### **Purpose**

To demonstrate methods of making shelters and beds.

##### **Procedure**

1. Various types of overnight shelters, beds, reflector fires and fireplaces should be constructed at a given place and used for demonstration purposes.
2. Hike battalion to demonstration area, pointing out any natural shelters encountered en route.
3. Explain construction of shelters, beds, and fireplaces, and demonstrate various types of shelter, and signal fires.
4. Demonstrate how a parachute can be used as a tent, hammock, sleeping bag, and pack sack.
5. Demonstrate how a fire should be made with matches in dry and wet weather, then let platoons compete. Make certain that all fires are thoroughly extinguished.

6. On return hike let each platoon select a camp site; considering their selection in regard to one limiting factor that must be met in order to get a good night's sleep. That is: Instruct one platoon to select a site because it would be relatively free of mosquitoes, another one to make a selection with regard to protection from cold, or because bedding or shelter material is at hand, or because drinking water is available. Explain to the platoon why their selection is good or bad.

References—Chapter VI, pages 106-108; Chapter VII; Chapter IX, pages 187-188.

#### HIKE IV—FIREMAKING AND COOKING

##### *Purpose*

To give cadets the experience of making a fire and cooking a meal.

##### *Procedure*

1. Issue available equipment deemed necessary for hike and carry food for one meal. If possible take foods that can be cooked without cooking utensils, as would be the case with most wild foods utilized in an emergency.
2. Hike to demonstration area. Let each cadet make a fire and roast a half fowl and bake potatoes in mud or stone-lined pit ovens. Cook a few samples of wild foods, such as cattail roots, arrowhead bulbs or potherbs.
3. If green bamboo, coconut shells or sea shells can be obtained, demonstrate cooking in these utensils.
4. While food is cooking, point out and gather various tinders which can be used to start a fire with a lens from a flashlight, camera or binoculars. Demonstrate how such a fire is made. At a given signal, let several cadets from each platoon produce blazing tinder.
5. Construct various types of cooking fires for demonstration purposes.

Reference—Chapter VI.

#### HIKE V—CLIMBING TECHNICS

##### (A)—(ROPE WORK)

##### *Purpose*

To instruct the cadets in rope technics necessary for getting out of rough, canyon, or mountainous country, and useful in abandoning ship.

##### *Procedure*

1. Hike to cliff, quarry, canyon or high wall where there is a steep or perpendicular drop of 20 or 30 feet.
2. Divide the battalion into platoons and demonstrate rappelling and climbing in a Spanish bowline.
3. Let each cadet rappell down the drop.
4. Instruct cadets concerning the dangers and necessary precautions that must be observed in rock climbing.

FIG. 313. Cadets Sample the Starchy Root of the Cattail. Edible Plants Should Be Pointed Out on All Hikes.

FIG. 314. Demonstrating How Water Can Be Obtained from a Vine

5. Demonstrate how a rope can be made from parachute shroud lines.
6. Demonstrate and practice useful knots.

Reference—Chapter II, pages 31-37.

### HIKE V(B)—(TREE CLIMBING)

**Purpose**

To instruct the cadets in the various methods of climbing trees.

**Procedure**

1. Hike to wooded area.
2. Platoon officers demonstrate the following methods of climbing trees.
  - (a) Shinnying.
  - (b) Use of low limbs or vines.
  - (c) Use of a rope.
  - (d) Native method for climbing palms.
3. Demonstrate precautions that should be taken when climbing trees.
4. At given signal let each cadet attempt to climb a tree to a height of 25 ft. and take a compass reading on a distant landmark.
5. Order cadets to change trees and repeat performance.

Reference—Chapter II, pages 38-39.

### HIKE VI—TRAVEL HAZARDS

#### (A) (RAFT CONSTRUCTION)

**Purpose**

To demonstrate construction of a raft and impart information and give practical instruction on inland water travel.

**Procedure**

1. Hike battalion along wooded creek or river bottom, fording the stream at several points. Demonstrate technics of fording streams under various water conditions.
2. Point out trees whose bark can be used for cord or lashing.
3. Using logs previously gathered for the purpose, construct a raft with bark lashing.
4. Practice poling the raft and give instructions on inland water travel.

References—Chapter II, pages 17-37; Chapter IV, pages 104-105.

### HIKE VI(B)—(SWIMMING IN SURF AND DEEP OR SHALLOW RAPIDS)

**Purpose**

To give cadets the experience of swimming in swift or rough water such as is likely to be encountered in traveling any distance back to a base.

**Note**

This exercise must be carried out with careful supervision and caution.

FIG. 315. Instructing Cadets Concerning the Poisonous Snakes Found Near the Base

**Procedure**

1. When rapids are conveniently close, demonstrate how to swim down shallow and deep rapids. Demonstrate how to swim in a current. Let each cadet practice when possible. Swim in clothes.
2. If near the seashore, locate a rip current and show cadets how to swim out of it. Let them practice this and practice going in and out through a moderate surf.
3. If there are lakes, ponds, or lagoons containing aquatic vegetation, plan an exercise to acquaint cadets with methods of swimming through such water. Don't avoid mud.

Reference—Chapter II, pages 20-28.

**HIKE VI(C)—(TRAVELING THROUGH SWAMPS,  
BOGS OR QUICKSAND)****Purpose**

To eliminate fear of these hazards by showing cadets what they can do when such hazards are encountered.

**Note**

The greatest value of this exercise and the preceding one is the confidence a cadet attains from the experience.

**Procedure**

1. If a swamp, bog, or quicksand is located near the base, plan a hike to this area and show the cadets how to swim or work their way through the mud, water and vegetation. Explain and demonstrate what to do if caught in a bog.
2. Take ropes along to encourage those who are poor swimmers, and instruct men to wear fatigue clothes.
3. See that each cadet actually goes through the exercise.
4. If there is no treacherous bog or sand, hike the cadets through several miles of swamp or marsh land or along a river bottom. Follow a compass bearing, and don't detour natural obstacles.
5. Plan a platoon race over part of the distance.
6. Explain possible dangers from snakes, crocodiles, leeches and flukes that might be encountered in such places in other parts of the world.

References—Chapter II, pages 28-31; Chapter IX, pages 199-213.

**HIKE VI(D)—(NIGHT HIKE)****Purpose**

To instruct the cadets how to travel alone at night in unfamiliar country using a map and compass.

**Procedure**

1. Map a route that will intersect wooded and open country, and if possible,

include a stream, swamp, or ridge. It is well to have each change of course begin and end with a definite landmark.

2. Issue compasses to each cadet and maps to at least every five men.
3. Do not use lights except when absolutely necessary.
4. Plan the route so several different bearings must be followed.
5. When following one of these bearings, use only stars and skyline to keep the course, and do not use compass after once determining the direction of travel except occasionally to check bearing.
6. Point out the Big and Little Dipper, North Star and any constellations that may be of interest. Show cadets how to keep a course using compass and stars in combination.
7. Emphasize traveling quietly. This can be demonstrated by starting half of the men hiking toward the other half from the end of the course. Let these men stop and ambush oncoming ones.
8. Wear mosquito head nets for part of the hike, or if necessary, for the entire hike.
9. In rough country a hike of three or four miles will be sufficient. (See pages 232-233)

Reference—Chapter II, pages 9-17.

#### HIKE VII—TRAPPING AND FISHING

##### *Purpose*

To acquaint cadets with the principles of stalking and to demonstrate the construction of a few simple snares, fishing lines and hooks.

##### *Procedure*

1. At demonstration area explain construction and use of hanging snares, bird snares and deadfalls.
2. Point out animal signs such as: tracks, feces, feeding areas and beds that indicate where to hunt or trap.
3. On an overnight hike set a few rabbit snares.
4. Demonstrate how fishing lines can be made from bark. Fashion makeshift hooks and where possible allow cadets to fish with lines and hooks of their own construction.

References—Chapter V; Chapter VIII, pages 136-138.

#### HIKE VIII—OVERNIGHT HIKE

##### *Purpose*

To give cadets practical camping experience.

##### *Note:*

Two or more overnight hikes or camping trips are strongly recommended, and where possible, should wind up the instruction period, affording both a review and a chance to impart additional experiences.

FIG. 316. Training Equipment for One Man.

FIG. 317. Equipment Should Be Stored so as to Be Quickly Available and Easily Checked

**Procedure**

1. It is suggested that overnight trips be planned on week-ends and whenever there is a period of inactivity following completion of the Pre-Flight Training, such as occurs when cadets are held over awaiting future assignment.
2. Issue K rations and complete equipment.
3. Select a suitable campsite as a destination. It should be a clearing near a body of water and make certain that suitable drinking water is available, or is carried along.
4. Hike to camping area and prepare camp, beds and evening meal.
5. Conduct a two-hour night hike. (See pages 232-233.)
6. Prepare breakfast.
7. Hike in small units to a designated area, using maps and compass.
8. Follow compass bearing back to base. If time and facilities are available incorporate the following exercises.
  - (a) Practice raft construction and poling.
  - (b) Give additional rope work.
  - (c) Plan competitive exercises in firemaking and shelter construction.
  - (d) Practice with emergency signalling mirrors.

Reference—Chapter II.

**HIKE IX—COLD WEATHER HIKE****Purpose**

To give cadets the experience of preparing a shelter and a meal in cold weather, and to impress on them the necessity for being dressed and prepared for such weather.

**Procedure**

1. Instruct cadets in proper cold weather attire before taking hike.
2. When winter weather conditions exist, hike cadets to a wooded area and point out the most protected camp sites.
3. Demonstrate the construction of snow or combination snow and bough bivouac as illustrated in manual.
4. Build a windbreak and impress on the cadets the necessity of sleeping out of the wind.
5. Construct a demonstration bough bed and reflector fire.
6. If possible, let each cadet cook a meal and melt snow for cooking and drinking purposes.
7. Instruct cadets how to keep warm with a minimum of equipment. Warn them of the danger of sweating in cold weather, and how to prevent it.
8. Point out animal tracks in the snow, and show where snares could be set effectively, and where to look for winter food.
9. Many of the hikes already outlined can be and should be adapted to cold

FIG. 318. Adjusting Packs to Fit the Individual

FIG. 319. A Battalion of Cadets Starting an Overnight Hike

weather. Make an overnight hike when possible, using equipment. References—Chapter VII; Chapter IX, pages 183-188.

#### HIKE X—CROSS-COUNTRY OVERNIGHT TEST HIKE

##### **Purpose**

To test the speed, endurance and skill of cadets in traveling over rough country.

##### **Note**

The best possible training for an emergency is to have had previous experience in a similar predicament and to have worked a way out. Therefore a planned exercise, simulating as nearly as possible the conditions as pilot will encounter and the activities he must perform when stranded in a wilderness area, will be of great value in enabling him to automatically do the right thing in the real pinch.

##### **Procedure**

1. Lay out on an aerial map a 10 or 20 mile course that will intersect streams, swamps, hills, and wooded country.
2. Furnish each cadet with a map and have them carry only emergency equipment and K rations.
3. Instruct them to dress adequately for any weather conditions that might arise and to carry a change of clothes.
4. Caution against fire hazards.
5. Drop cadets from busses in pairs or small units with instructions to hike until dark, make camp, and to arrive at the base at a designated time the following day.

#### EXTENDED TRAINING PERIOD

The ideal method for imparting survival experience and training is to arrange a full week of continuous field work. At times this will be possible among holdover groups. For such occasions prepare an aerial map with a marked route of travel. Follow a roughly circular course (50 to 75 miles long) through wooded country, and along streams and river bottoms. Previously determine the camp site for each night. Carry full packs with food for several days. Additional food may be picked up where the route of travel crosses highways. Exercises already outlined should be modified to fit into each day's instruction.

#### DEMONSTRATION AREA

A demonstration camp site should be established and should be located near the base and have the following facilities:

1. Drinking water.
2. Adequate space for a battalion of men to camp.
3. Fireplaces.

FIG. 320. Sleeping Out

FIG. 321. Instruction for a Night Hike.

4. Trench latrines.
5. Incinerator.
6. Large hot water containers for washing mess gear.
7. Demonstration units containing:
  - (a) Various types of fireplaces and fires.
  - (b) Stone-lined pit ovens.
  - (c) Types of bough beds.
  - (d) Framework for smoking or drying meat.
  - (e) Types of shelters.
  - (f) Types of snares.
  - (g) Parachute used as a tent, hammock, sleeping bag and back pack.
  - (h) Common snakes of the area.
  - (i) Permanent shelter for equipment.

The purpose of the demonstration area is to enable instructors to impart certain information and technics to the men quickly. It should not take the place of field trips but should be included as part of the over-all survival program and be used in connection with the field exercises whenever demonstration procedures are most practical.

## EQUIPMENT

The following equipment has been carefully selected and is adequate for carrying out the Survival Program in a Pre-Flight School.

### *Equipment for a Battalion of 300 Men and Officers*

- 175 Tents
- 350 Rucksacks
- 350 Canteens
- 350 Compasses
- 350 Individual mess kits
- 175 12" blade machetes
- 350 Sleeping bags with water-repellent covering
- 12 Jungle hammocks
- 350 Mosquito head nets
- 350 Emergency signalling mirrors
- 10 Emergency fishing kits
  - Supply of waterproof matches
  - Supply of K rations
- Topographic and aerial maps of the base and vicinity covering a radius of 10 or 20 miles

## CARE OF EQUIPMENT

A single man-unit of equipment should contain all individual units, such

FIG. 322. Cleaning Mess Gear at Camping and Demonstration Area

as sleeping bag, canteen, and compass (in the pack) and each piece should be numbered to correspond to the number on the pack.

Wet sleeping bags, tents, and packs must be spread out and thoroughly dried before repacking. Mess gear must be kept clean and dry.

## OUTLINE OF SURVIVAL PROGRAM

### PRE-FLIGHT INSTRUCTION

1. Five to eight illustrated lectures, and six to eight field trips covering material in this manual.

The aim of this phase of instruction is to teach the basic principles and fundamentals of surviving on land and sea and to give the cadets a general knowledge of survival based on actual experience.

### INTERMEDIATE AND OPERATIONAL INSTRUCTION

1. Demonstration of various types of emergency equipment to familiarize the men with its use.
  - (a) Emergency sea equipment
  - (b) Emergency jungle equipment
  - (c) Emergency arctic equipment
2. Illustrated lectures covering specific survival information on special areas of operation.
  - (a) South Pacific
  - (b) Aleutian area
  - (c) Africa

### ADVANCED BASE INSTRUCTION

It is suggested that if training centers for imparting survival information to naval aviators are established in the Aleutian and South Pacific areas, the training at such centers cover material relating to specific conditions in the area and that where possible field instruction be given.

## Glossary and Scientific Terminology

African puff adder—*Bitis arietans*

African walnut or gabon—*Coula*

Air plants, epiphyte—a plant attached above ground to another plant

Alder—*Alnus*

Amanita—a group or genus of poisonous mushrooms

Amphibians—animals such as frogs, toads, newts and salamanders

Anaconda, water boa—*Eunectes*

Archipelago—sea or large body of water interspersed with islands

Aroids—a group of plants generally containing stinging crystals of calcium oxalate and belonging to the calla lily family (*Araceae*)

Aspen—*Populus*

Atabrine—drug used in treating malaria

Australasia—Australia and adjacent islands

Australian black snake—*Pseudechis porphyriacus*

Australian needle bush—*Hakea leucoptera*

Australian nut trees—*Macadamia*

Badu, Coco—*Xanthosoma violaceum*

Bamboo snakes—*Trimeresurus*

Baobab tree—*Adansonia*

Barrel cactus—*Echinocactus*

Basswood—*Tilia*

Beaded lizard—*Heloderma horridum*

Beech family—*Fagaceae*

Betel nuts—*Areca catechu*

Bitter manioc—*Manihot esculenta*

Bivalve—an animal with a two-valve shell like an oyster

Black birch—*Betula lenta*

Black snake—*Coluber*

Black widow spider—*Latrodectes*

Bloodwood—*Eucalyptus terminalis*

Boas and pythons—*Boidae*

Bottle tree—*Brachychiton*

Brake fern—*Pteris*

Bushmaster—*Lachesis mutus*

Butternuts—*Juglans*

Calla lily—*Calla palustris*  
Cape viper—*Causus rhombeatus*  
Carnivores—mammals that feed chiefly on meat such as tigers, wolves, bears  
Caster oil plant—*Ricinus*  
Cheetal—Indian spotted deer  
Chinese lacquer tree—*Rhus verniciflua*  
Climbing hemp weed—*Mikania scandens*  
Copperhead—*Agkistrodon*  
Coral snake—*Micruurus*  
Coulter pine—*Pinus coulteri*  
Death adder—*Acanthophis antarcticus*  
Desert oak—*Casuarina decaisneana*  
Elephant ear—*Alocasia macrorhiza*  
Emodi pine—*Pinus longifolia*  
Euphorbias—spurges  
Feces—animal excrement  
Fer-de-lance—*Bothrops atrox*  
Frond—the leaf of ferns  
Fig trees—*Ficus*  
Fireweed (northern)—*Epilobium latifolium*  
Flukes—parasitic flat worms  
Garter snake—*Thamnophis*  
Genus—a related group of plants or animals containing one or more species that are structurally similar  
Genera—plural of genus  
Gila monster—*Heloderma suspectum*  
Goatsuckers—*Caprimulgus*—Whippoorwill-like bird  
Great white shark—*Carcharodon carcharias*  
Gray nurse shark—*Carcharias*  
Hardwoods—hickory, oaks, ironwoods, locust, birches, sugar maple, ash, holly, etc.  
Heath—*Ericaceae*  
Hemlock—*Tsuga*  
Herbaceous—green succulent plants as compared with woody ones  
Herbivorous—feeding on plants—animals such as deer, antelope, buffalo  
Humus—black or brown organic soil formed from the partial decomposition of vegetable and animal matter  
Iguanas—large lizards found in Tropical America  
Jack-in-the-pulpit, Indian turnip—*Arisaema triphyllum*

King cobra, hamadryad—*Naja hannah*  
Korean pine—*Pinus koraiensis*  
Labrador tea—*Ledum latifolium*  
Lemming—small mouse-like rodents  
Lianas—tropical vines  
Limber pine—*Pinus flexilis*  
Lodgepole pine—*Pinus contorta*  
Lymphatics—vessels within the body containing or conveying lymph  
Machete—a large heavy knife  
Malay Archipelago—Malay Peninsula and adjacent islands  
Mangrove trees—*Rhizophora*—one of the more common of many genera  
Millets—*Setaria*  
Mints—plants belonging to the *Labiatae* family—usually have square stems and opposite aromatic leaves  
Monitors—large Old World lizards  
Morels—*Morchella*  
Mountain sorrel—*Oxyria digyna*  
Nepal nut pine—*Pinus gerardiana*  
Omnivorous—eating a wide variety of plant and animal food  
Osage orange—*Maclura*  
Palmate—leaflets of leaf radiate out from stem like fingers on a hand  
Palm Vipers—*Bothrops*  
Papain—a protein splitting enzyme  
Parching—(corn)—to dry or scorch over a fire until brown and brittle  
Pemmican—a concentrated ration of dried, ground meat mixed with melted fat  
Poplars—*Populus*  
Pine Family—*Pinaceae*  
Pinnate—leaf with leaflets arranged on each side of stem like walnut leaf. (See fig. 67)  
Pinon pine—*Pinus edulis*  
Poisonous long fanged snakes—*Viperidae* and *Crotalidae*  
Poisonous short fanged snakes—*Elapidae*  
Poke weed—*Phytolacca*  
Portuguese-men-of-war—*Physalia*  
Prawns—shrimp-like crustaceans  
Prickly pears—*Opuntia*  
Quinine—drug used in treating malaria  
Regal python—*Python reticulatus*

Rengas trees—trees belonging to the genera *Gluta*, *Melanochyla*, *Melanorrhea*, *Semecarpus* and *Swintonia*

Russell's viper—*Vipera russellii*

Sambar—Indian deer

Sand grouse—*Pterocles*

Sand shark—*Carcharias*

Sapodilla tree—*Achras sapota*

Sassafras—*Sassafras officinale*

Scotch pine—*Pinus sylvestris*

Sea snakes—*Hydridae*

Single leaf pine—*Pinus monophylla*

Skunk cabbage—*Symplocarpus foetidus*

Softwoods—examples—most pines, willows, spruce, basswood, yellow poplar, aspen, red cedar, alder, etc.

Sorghums—a genus of grasses

Species—a plant or animal with characteristics that distinguish it from all other members of a group or genus. In a scientific name the species name follows the genus name as in *Typha latifolia*. The species name is *latifolia*

Spicebush—*Benzoin*

Spruce—*Picea*

Spurge family—*Euphorbiaceae*

Star apple—*Chrysophyllum africanum*

Stinging plants—examples—*Tragia*, *Mucuna*, *Jatropha*, *Ortega*, fruits and leaves of various palms

Strychnine trees—*Strychnos*

Sugar pine—*Pinus lambertiana*

Sumach—*Rhus*

Swiss stone pine—*Pinus cembra*

Tamarack—*Larix*

Tiger shark—*Galeocerdo articus*

Tiger snake—*Notechis scutatus*

Traveler's tree—*Ravenala madagascariensis*

Tree nettles—*Laportea*

Tubers—thick, roundish underground stems that store food for the plant

Umbrella tree—*Musanga Smithii*

Upas or Ipoh tree—*Antiaris toxicaria*

Voles—field mice

Walnuts—*Juglans*

Water hemlock—*Cicuta maculata*

Water moccasin—*Agkistrodon Piscivorus*

Water tree or vine—*Tetracera potatoria*

Water trees—various species of *Eucalyptus* called "Mallees."

*Eucalyptus microtheca*, *E. incrassata*, *E. oleosa*, *E. paniculata*, *E. populifolia*

Other species of *Eucalyptus* known as Tasmanian Cider trees (*E. Gunnii*) (*E. resinifera*) (*E. mannifera*) yield a refreshing liquid in the spring from cuts made in the bark.

White heather—*Cassiope tetragona*

Wild oats—*Avena*

Willows—*Salix*

Wintergreen—*Gaultheria*
